INTRODUCTION

The **MOSEK** Optimization Suite 8.0.0.74 is a powerfull software package capable of solving large-scale optimization problems of the following kind:

- linear,
- convex quadratic,
- conic quadratic (also known as second-order cone),
- semidefinite,
- and general convex.

Integer constrained variables are supported for all problem classes except for semidefinite and general convex problems. In order to obtain an overview of features in the **MOSEK** Optimization Suite consult the product introduction guide.

1.1 Why the Fusion API for .NET?

Fusion is an object oriented API specifically designed to build conic optimization models in a simple and expressive manner, using mainstream programming languages.

With focus on usability and compactness, it helps the user focus on the modeling instead of coding.

The most widespread class of optimization problems is *linear optimization problems*, where all relations are linear. The tremendous success of both applications and theory of linear optimization can be ascribed to the following factors:

- The required data are simple, i.e. just matrices and vectors.
- Convexity is guaranteed since the problem is convex by construction.
- Linear functions are trivially differentiable.
- There exist very efficient algorithms and software for solving linear problems.
- Duality properties for linear optimization are nice and simple.

Even if the linear optimization model is only an approximation to the true problem at hand, the many advantages of linear optimization may outweight the disadvantages. In some cases, however, the problem formulation is inherently nonlinear and a linear approximation is either intractable or inadequate. *Conic*

optimization has proved to be a very expressive and powerful way to introduce nonlinearities, while preserving all the nice properties of linear optimization listed above.

The fundamental expression in linear optimization is a linear expression of the form

$$Ax - b \in \mathcal{K}$$

where $\mathcal{K} = \{y : y \geq 0\}$, i.e.,

$$Ax - b = y,$$

$$y \in \mathcal{K}.$$

In conic optimization a wider class of convex sets \mathcal{K} is allowed, for example in 3 dimensions \mathcal{K} may correspond to an ice cream cone. The conic optimizer in **MOSEK** supports three structurally different types of cones \mathcal{K} , which allows a surprisingly large number of nonlinear relations to be modeled (as described in the **MOSEK** modeling cookbook), while preserving the nice algorithmic and theoretical properties of linear optimization.

A typical (low-level) solver API requires the problem to be serialized into a single matrix and a few vectors, and constructing (or modifying) such a problem often proves to be both a time-consuming and error-prone process. *Fusion*, on the other hand, introduces a higher level of abstraction, which allows the user to focus explicitly on modeling oriented aspects rather than reformulating a given model for a particular solver API. For example, in *Fusion* it is easy to add variables and constraints to an existing model.

Typically a conic optimization model in *Fusion* can be developed in a fraction of the time compared to using a low-level C API, but of course *Fusion* introduces a computational overhead compared to customized C code. In most cases, however, the overhead is small compared to the overall solution time, and we generally recommend that *Fusion* is used as a first step for building and verifying new models. Often, the final *Fusion* implementation will be directly suited for production code, and otherwise it readily provides a reference implementation for model verification.

1.2 License agreement

Before using the **MOSEK** software, please read the license agreement available in the distribution at <MSKHOME>/mosek/8/mosek-eula.pdf or on the **MOSEK** website https://mosek.com/sales/license-agreement.

MOSEK uses some third-party open-source libraries. Their license details follows.

zlib

MOSEK includes the *zlib* library obtained from the zlib website. The license agreement for *zlib* is shown in Listing 1.1.

Listing 1.1: zlib license.

zlib.h -- interface of the 'zlib' general purpose compression library version 1.2.7, May 2nd, 2012

fplib

MOSEK includes the floating point formatting library developed by David M. Gay obtained from the netlib website. The license agreement for *fplib* is shown in Listing 1.2.

Listing 1.2: fplib license.

INSTALLATION

In this section we discuss how to install and setup the MOSEK Fusion API for .NET.

2.1 Compatibility

Fusion .NET requires 4.5 and later.

2.2 Instructions

The relevant library mosekdotnet.dll is located in the folder <MSKHOME>/mosek/8/tools/platform/<PLATFORM>/bin where

- <PLATFORM> is either linux64x86 or osx64x86.
- <MSKHOME> is the root of the MOSEK installation.

2.3 Running Examples

The examples directories contain scripts for building and running the various examples; these are called build.bat and run.bat on Windows, and build.sh and run.sh on Linux and Mac OS X. Running all examples and making sure that all complete with no error is a recommended preliminary step to check that **MOSEK** Fusion is properly set up.

Note: A valid license must be available and set up.

GUIDELINES

3.1 Known Limitations

The main limitation in the use of the MOSEK Fusion API for .NET 8.0.0.74 are reported in this section.

3.1.1 Modeling Limitations

To design an API that looks almost the same across several programming languaes, some limitations are needed:

Fusion imposes some limitations on certain aspects of a model:

- Constraints and variables belong to a single model, and cannot as such be used (e.g. stacked) with objects from other models.
- Constraint and variable domains are immutable.

3.1.2 Memory Limitations

There are some hard limits on shapes and sizes in Fusion:

- The maximum number of variable elements used in a model can be no larger than $2^{31} 1$.
- The maximum size of a dimension is $2^{31} 1$.
- For efficiency reasons the total size of an item (the product of the dimensions) is limited to $2^{63} 1$.

Fetching a solution from a shaped variable produces a flat array of values. This means that all values, even the ones that are not used in the problem, are returned, and that the variable elements are linearly indexed. In this case, it is better to create a slice variable holding the relevant elements and fetch the solution for this; fetching the full solution may cause an exception due to memory exhaustion or platform-dependant constraints on array sizes.

Users might experience memory leaks using Fusion:

- memory usage not decreasing after the solver terminates.
- memory usage increasing during the resolution of a sequence of problems.

In both cases the reason might be due to **MOSEK** not releasing all the memory allocated by the <code>Model</code> class. Each <code>Model</code> object links to an external resource (the **MOSEK** task). Due to the way the garbage collector works it is not guaranteed when the <code>Model</code> object can be reclaimed, and in some cases it cannot be automatically reclaimed at all. This means that substantial amounts of memory may be leaked.

For this reason it is very important to always make sure that the <code>Model</code> object is properly disposed of when it is not used anymore by calling <code>Model.__del__()</code>.

Despite this operation might seems redundant in some situations, i.e. when a single problem of moderate size must be solved, it is a good practice to always take care of the memory management. This simple

steps will result in a more robust code, and less probability of future memory issues. The Model supports the Context Manager protocol, which means that by using the construction

```
using (MyModel M = new MyModel())
{
   // do something with M
}
```

ensures that <code>__del__()</code> is called when the with-scope ends, even if an exception was raised. If this cannot be used, e.g. if the <code>Model</code> object is returned by a factory function, the method must be explicitly called. Furthermore, if the <code>Model</code> class is inherited and any work is done in the constructor, it is necessary to ensure that if an exception is thrown during construction, the <code>Model.__del__()</code> is called. To ensure this, use a construction along the lines

```
class MyModel : Model
{
  public MyModel()
    : base()
{
    bool finished = false;
    try
    {
        // perform initialization here
        finished = true;
    }
    finally
    {
        if (! finished)
            Dispose();
    }
}
```

Note that this construction avoids having to catch and rethrow an exception in the constructor, thus changing the exception stack trace.

3.2 Deployment

When redistributing a .NET application using the **MOSEK** Fusion API for .NET 8.0.0.74, the following libraries must be included:

64-bit Windows	32-bit Windows
mosek64_8_0.dll	mosek32_8_0.dll
libomp5md.dll	libomp5md.dll
mosekxx8_0.dll	mosekxx8_0.dll
cilkrts20.dll	cilkrts20.dll
mosekdotnet.dll	mosekdotnet.dll

3.3 The license system

MOSEK is a commercial product that **always** needs a valid license to work. A license is typically provided as a license file that allows the user to access the subset of the **MOSEK** Optimization Suite functionalities it is entitled for, and for the right amount of time. **MOSEK** uses a third party license manager to implement license checking.

By default a license token remains checked out for the duration of the MOSEK session, i.e.

1. a license token is checked out when the method Model.solve is called the first time and

2. it is returned when the Model class instance is destroyed.

To change the license systems behavior to returning the license token after each call to **MOSEK** set the parameter <code>cacheLicense</code> to <code>off</code>.

Additionally license checkout and checkin can be controlled manually accessing the unerlying MOSEK task and environment. Please see Section 8.4.

3.3.1 Waiting for a free license

By default an error will be returned if no license token is available. By setting the parameter <code>licenseWait</code> MOSEK can be instructed to wait until a license token is available.

See section 8.1.

3.3.2 Manually stopping the license system

BASIC TUTORIALS

In this section a number of examples is provided to demonstrate the functionality required for solving linear, conic, semidefinite and quadratic problems as well as mixed integer problems.

- Linear optimization tutorial: It shows how to input a linear program. It will show how
 - define variables and their bounds,
 - define constraints and their bounds,
 - define a linear objective function,
 - input a linear program but rows or by column.
 - retrieve the solution.
- Conic quadratic optimization tutorial : The basic steps needed to formulate a conic quadratic program are introduced:
 - define quadratic cones,
 - assign the relevant variables to their cones.
- Semidefinite optimization tutorial : How to input semidefinite optimization problems is the topic of this tutorial, and in particular how to
 - input semidefinite matrices and in sparse format,
 - add semidefinite matrix variable and
 - formulate linear constraints and objective function based on matrix variables.
- ullet Mixed-Integer optimization tutorial: This tutorial shows how integrality conditions can be specified.

4.1 Linear Optimization

The simplest optimization problem is a purely linear problem. A *linear optimization problem* is a problem of the following form:

Minimize or maximize the objective function

$$\sum_{j=0}^{n-1} c_j x_j + c^f$$

subject to the linear constraints

$$l_k^c \le \sum_{j=0}^{n-1} a_{kj} x_j \le u_k^c, \quad k = 0, \dots, m-1,$$

and the bounds

$$l_j^x \le x_j \le u_j^x, \quad j = 0, \dots, n - 1,$$

where we have used the problem elements:

- m and n which are the number of constraints and variables respectively,
- x which is the variable vector of length n,
- \bullet c which is a coefficient vector of size n

$$c = \left[\begin{array}{c} c_0 \\ \vdots \\ c_{n-1} \end{array} \right],$$

- c^f which is a constant,
- A which is a $m \times n$ matrix of coefficients is given by

$$A = \begin{bmatrix} a_{0,0} & \cdots & a_{0,(n-1)} \\ \vdots & \cdots & \vdots \\ a_{(m-1),0} & \cdots & a_{(m-1),(n-1)} \end{bmatrix},$$

- l^c and u^c which specify the lower and upper bounds on constraints respectively, and
- l^x and u^x which specifies the lower and upper bounds on variables respectively.

Note: Please note the unconventional notation using 0 as the first index rather than 1. Hence, x_0 is the first element in variable vector x.

4.1.1 Example LO1

The following is an example of a linear optimization problem:

maximize
$$3x_0 + 1x_1 + 5x_2 + 1x_3$$

subject to $3x_0 + 1x_1 + 2x_2 = 30$,
 $2x_0 + 1x_1 + 3x_2 + 1x_3 \ge 15$,
 $2x_1 + 3x_3 \le 25$,
$$(4.1)$$

having the bounds

$$0 \leq x_0 \leq \infty,
0 \leq x_1 \leq 10,
0 \leq x_2 \leq \infty,
0 \leq x_3 \leq \infty.$$

We start our implementation in Fusion importing the relevant modules, i.e.

```
using mosek.fusion;
```

Next we declare an optimization model creating an instance of the Model class:

```
Model M = new Model("lo1");
```

From now on most of our steps will involve M. The variables in problem (4.1) can be declared specifying:

- an (optional) name,
- their dimension,
- the bounds.

```
// Create variable 'x' of length 4
Variable x = M.Variable("x", 4, Domain.GreaterThan(0.0));
```

It is important to notice that the bound will be applied element-wise.

To define the constraints, we assume the coefficient matrix to be given as an array of rows A, each one being a dense array as well.

```
M.Constraint("c1", Expr.Dot(A[0], x), Domain.EqualsTo(30.0));
M.Constraint("c2", Expr.Dot(A[1], x), Domain.GreaterThan(15.0));
M.Constraint("c3", Expr.Dot(A[2], x), Domain.LessThan(25.0));
```

We end the definition of our optimization model setting the objective function: the coefficient are assumed to be given in a single one dimensional array c.

```
M.Objective("obj", ObjectiveSense.Maximize, Expr.Dot(c, x));
```

Finally, we only need to call the Model.solve method:

```
M.Solve();
```

The values attained by each variable can be obtained using the Variable.level method.

The complete code follows in Listing 4.1.

Listing 4.1: Fusion implementation of model (4.1).

```
using System;
using mosek.fusion;
namespace mosek
 namespace fusion
    namespace example
      public class 101
        public static void Main(string[] args)
          double[][] A =
            { new double[] { 3.0, 2.0, 0.0, 1.0 },
              new double[] { 2.0, 3.0, 1.0, 1.0 },
              new double[] { 0.0, 0.0, 3.0, 2.0 } };
          double[] c = { 3.0, 5.0, 1.0, 1.0 };
          // Create a model with the name 'lo1'
          Model M = new Model("lo1");
          // Create variable 'x' of length 4
          Variable x = M.Variable("x", 4, Domain.GreaterThan(0.0));
          // Create three constraints
          M.Constraint("c1", Expr.Dot(A[0], x), Domain.EqualsTo(30.0));
           \begin{tabular}{ll} M. Constraint("c2", Expr.Dot(A[1], x), Domain.GreaterThan(15.0)); \end{tabular} 
          \label{eq:m.constraint("c3", Expr.Dot(A[2], x), Domain.LessThan(25.0));} \\
          // Set the objective function to (c^t * x)
          M.Objective("obj", ObjectiveSense.Maximize, Expr.Dot(c, x));
          // Solve the problem
          M.Solve();
          // Get the solution values
```

4.2 Conic Quadratic Optimization

Conic optimization is a generalization of linear optimization, allowing constraints of the type

$$x^t \in \mathcal{K}_t$$

where x^t is a subset of the problem variables and \mathcal{K}_t is a convex cone. Actually, since the set \mathbb{R}^n of real numbers is also a convex cone, all variables can in fact be partitioned into subsets belonging to separate convex cones, simply stated $x \in \mathcal{K}$.

MOSEK can solve conic quadratic optimization problems of the form

minimize
$$c^{T}x + c^{f}$$
subject to
$$l^{c} \leq Ax \leq u^{c},$$

$$l^{x} \leq x \leq u^{x},$$

$$x \in \mathcal{K},$$

where the domain restriction, $x \in \mathcal{K}$, implies that all variables are partitioned into convex cones

$$x = (x^0, x^1, \dots, x^{p-1}), \text{ with } x^t \in \mathcal{K}_t \subseteq \mathbb{R}^{n_t}.$$

For convenience, the user only specify subsets of variables x^t belonging to cones \mathcal{K}_t different from the set \mathbb{R}^{n_t} of real numbers. These cones can be a:

• Quadratic cone:

$$Q^{n} = \left\{ x \in \mathbb{R}^{n} : x_{0} \ge \sqrt{\sum_{j=1}^{n-1} x_{j}^{2}} \right\}.$$

• Rotated quadratic cone:

$$Q_r^n = \left\{ x \in \mathbb{R}^n : 2x_0 x_1 \ge \sum_{j=2}^{n-1} x_j^2, \quad x_0 \ge 0, \quad x_1 \ge 0 \right\}.$$

From these definition it follows that

$$(x_4, x_0, x_2) \in \mathcal{Q}^3$$
,

is equivalent to

$$x_4 \ge \sqrt{x_0^2 + x_2^2}.$$

Furthermore, each variable may belong to one cone at most. The constraint $x_i - x_j = 0$ would however allow x_i and x_j to belong to different cones with same effect.

4.2.1 Example CQO1

We want to solve the following Conic Optimization Problem:

$$\min_{s.t.} y_1 + y_2 + y_3
s.t.
 x_1 + x_2 + 2.0x_3 = 1.0
 x_1, x_2, x_3 \ge 0.0
 (y_1, x_1, x_2) \in \mathcal{Q}^3,
 (y_2, y_3, x_3) \in \mathcal{Q}^3_r$$
(4.2)

is an example of a conic quadratic optimization problem. The problem involves some linear constraints, a quadratic cone and a rotated quadratic cone.

We start creating the optimization model:

```
using (Model M = new Model("cqo1"))
{
```

We than define variables x and y, the former non negative, the latter free. Two logical variables z1 and z2 are introduced as they will be used to define the second order cones.

```
Variable x = M.Variable("x", 3, Domain.GreaterThan(0.0));
Variable y = M.Variable("y", 3, Domain.Unbounded());

// Create the aliases
// z1 = [ y[0],x[0],x[1] ]
// and z2 = [ y[1],y[2],x[2] ]
Variable z1 = Var.Vstack(y.Index(0), x.Slice(0,2));
Variable z2 = Var.Vstack(y.Slice(1,3),x.Index(2));
```

It is important to note that z1 and z2 are just logical variables, i.e. just map onto x,y. They are introduced for convenience sake.

The linear constraint are defined simply multiplying an array of coefficients with x:

```
// Create the constraint
// x[0] + x[1] + 2.0 x[2] = 1.0
double[] aval = new double[] {1.0, 1.0, 2.0};
M.Constraint("lc", Expr.Dot(aval, x), Domain.EqualsTo(1.0));
```

The conic constraints are defined using the logical views z1 and z2:

```
// Create the constraints
// z1 belongs to C_3
// z2 belongs to K_3
// where C_3 and K_3 are respectively the quadratic and
// rotated quadratic cone of size 3, i.e.
// z1[0] > sqrt(z1[1]^2 + z1[2]^2)
// and 2.0 z2[0] z2[1] > z2[2]^2
Constraint qc1 = M.Constraint("qc1", z1.AsExpr(), Domain.InQCone());
Constraint qc2 = M.Constraint("qc2", z2.AsExpr(), Domain.InRotatedQCone());
```

Note that this is not the only way to define that conic constraints. But it is in this case probably the cleanest and faster.

We only need our objective function:

```
// Set the objective function to (y[0] + y[1] + y[2])
M.Objective("obj", ObjectiveSense.Minimize, Expr.Sum(y));
```

Just call the Model.solve method to run the solver:

```
M.Solve();
```

The solution can be retrieve using *Variable.level*, while the dual multipliers of the constraints are available via the *Variable.dual* method. For the linear part

```
// Get the linearsolution values
double[] solx = x.Level();
double[] soly = y.Level();
```

while the conic quadratic part can be retrieve easily as well.

```
// Get conic solution of qc1
double[] qc1lvl = qc1.Level();
double[] qc1sn = qc1.Dual();
```

The complete code follows in Listing 4.2.

Listing 4.2: Fusion implementation of model (4.2).

```
using System;
using mosek.fusion;
namespace mosek
 namespace fusion
   namespace example
     public class cqo1
       public static void Main(string[] args)
         using (Model M = new Model("cqo1"))
           Variable x = M.Variable("x", 3, Domain.GreaterThan(0.0));
           Variable y = M.Variable("y", 3, Domain.Unbounded());
           // Create the aliases
            // z1 = [y[0],x[0],x[1]]
            // and z2 = [y[1],y[2],x[2]]
           Variable z1 = Var.Vstack(y.Index(0), x.Slice(0,2));
           Variable z2 = Var.Vstack(y.Slice(1,3),x.Index(2));
           // Create the constraint
                  x[0] + x[1] + 2.0 x[2] = 1.0
           double[] aval = new double[] {1.0, 1.0, 2.0};
           M.Constraint("lc", Expr.Dot(aval, x), Domain.EqualsTo(1.0));
            // Create the constraints
           //
                 z1 belongs to C_{-}3
                   z2 belongs to K_3
            // where C_3 and K_3 are respectively the quadratic and
            // rotated quadratic cone of size 3, i.e.
                            z1[0] > sqrt(z1[1]^2 + z1[2]^2)
            // and 2.0 z2[0] z2[1] > z2[2]^2
           Constraint qc1 = M.Constraint("qc1", z1.AsExpr(), Domain.InQCone());
           Constraint qc2 = M.Constraint("qc2", z2.AsExpr(), Domain.InRotatedQCone());
            // Set the objective function to (y[0] + y[1] + y[2])
           M.Objective("obj", ObjectiveSense.Minimize, Expr.Sum(y));
```

```
// Solve the problem
          M.Solve();
           // Get the linearsolution values
           double[] solx = x.Level();
           double[] soly = y.Level();
           Console.WriteLine("x1,x2,x3 = \{0\}, \{1\}, \{2\}",solx[0],solx[1],solx[2]);
           Console.WriteLine("y1,y2,y3 = \{0\}, \{1\}, \{2\}", soly[0], soly[1], soly[2]);
           // Get conic solution of qc1
           double[] qc1lvl = qc1.Level();
           double[] qc1sn = qc1.Dual();
           Console.Write("qc1 levels = {0}", qc1lv1[0]);
           for (int i = 1; i < qc1lvl.Length; ++i)</pre>
            Console.Write(", {0}", qc1lvl[i]);
           Console.WriteLine();
           Console.Write("qc1 dual conic var levels = {0}", qc1sn[0]);
           for (int i = 1; i < qc1sn.Length; ++i)</pre>
            Console.Write(", {0}", qc1sn[i]);
           Console.WriteLine();
}
```

4.3 Semidefinite Optimization

Semidefinite optimization is a generalization of conic quadratic optimization, allowing the use of matrix variables belonging to the convex cone of positive semidefinite matrices

$$S_{+}^{r} = \left\{ X \in S^{r} : z^{T} X z \ge 0, \quad \forall z \in \mathbb{R}^{r} \right\},$$

where S^r is the set of $r \times r$ real-valued symmetric matrices.

MOSEK can solve semidefinite optimization problems of the form

$$\begin{array}{lll} \text{minimize} & \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \left\langle \overline{C}_j, \overline{X}_j \right\rangle + c^f \\ \text{subject to} & l_i^c & \leq & \sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \left\langle \overline{A}_{ij}, \overline{X}_j \right\rangle & \leq & u_i^c, & i = 0, \dots, m-1, \\ & l_j^x & \leq & x_j & \leq & u_j^x, & j = 0, \dots, n-1, \\ & & x \in \mathcal{K}, \overline{X}_j \in \mathcal{S}_+^{r_j}, & j = 0, \dots, p-1 \end{array}$$

where the problem has p symmetric positive semidefinite variables $\overline{X}_j \in \mathcal{S}_+^{r_j}$ of dimension r_j with symmetric coefficient matrices $\overline{C}_j \in \mathcal{S}^{r_j}$ and $\overline{A}_{i,j} \in \mathcal{S}^{r_j}$. We use standard notation for the matrix inner product, i.e., for $A, B \in \mathbb{R}^{m \times n}$ we have

$$\langle A, B \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} A_{ij} B_{ij}.$$

4.3.1 Example SDO1

The problem

is a mixed semidefinite and conic quadratic programming problem with a 3-dimensional semidefinite variable

$$\overline{X} = \begin{bmatrix} \overline{X}_{00} & \overline{X}_{10} & \overline{X}_{20} \\ \overline{X}_{10} & \overline{X}_{11} & \overline{X}_{21} \\ \overline{X}_{20} & \overline{X}_{21} & \overline{X}_{22} \end{bmatrix} \in \mathcal{S}_{+}^{3},$$

and a conic quadratic variable $(x_0, x_1, x_2) \in \mathcal{Q}^3$. The objective is to minimize

$$2(\overline{X}_{00} + \overline{X}_{10} + \overline{X}_{11} + \overline{X}_{21} + \overline{X}_{22}) + x_0,$$

subject to the two linear constraints

$$\overline{X}_{00} + \overline{X}_{11} + \overline{X}_{22} + x_0 = 1,$$

and

$$\overline{X}_{00} + \overline{X}_{11} + \overline{X}_{22} + 2(\overline{X}_{10} + \overline{X}_{20} + \overline{X}_{21}) + x_1 + x_2 = 1/2.$$

$$\min_{s.t.} Tr(\overline{C} \cdot \overline{X}) + x_0
s.t.$$

$$Tr(\overline{A}_0 \cdot \overline{X}) + x_0 = 1.0
Tr(\overline{A}_1 \cdot \overline{X}) + x_1 + x_2 = \frac{1}{2}
\underline{(x_0, x_1 x_2)} \in \mathcal{Q}^3
\overline{X} \in \mathcal{S}_+,$$

$$(4.4)$$

where

$$\overline{C} = \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}, \overline{A}_0 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \overline{A}_1 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}.$$

The complete code follows in Listing 4.3.

Listing 4.3: Fusion implementation of model (4.4).

```
public class sdo1
        public static void Main(string[] args)
          using (Model M = new Model("sdo1"))
            // Setting up the variables
            Variable X = M.Variable("X", Domain.InPSDCone(3));
            Variable x = M.Variable("x", Domain.InQCone(3));
            Matrix C = Matrix.Dense ( new double[,] { \{2,1,0\}, \{1,2,1\}, \{0,1,2\}\} );
            Matrix A1 = Matrix.Dense ( new double[,] { \{1,0,0\}, \{0,1,0\}, \{0,0,1\}} );
            Matrix A2 = Matrix.Dense (new double[,] { {1,1,1}, {1,1,1}, {1,1,1}} );
            // Objective
            M.Objective(ObjectiveSense.Minimize, Expr.Add(Expr.Dot(C, X), x.Index(0)));
            // Constraints
            M.Constraint("c1", Expr.Add(Expr.Dot(A1, X), x.Index(0)), Domain.EqualsTo(1.0));
            M.Constraint("c2", Expr.Add(Expr.Dot(A2, X), Expr.Sum(x.Slice(1,3))),
                         Domain.EqualsTo(0.5));
            M.Solve();
            Console.WriteLine("[{0}]", (new Utils.StringBuffer()).A(X.Level()).ToString());
            Console.WriteLine("[{0}]", (new Utils.StringBuffer()).A(x.Level()).ToString());
      }
   }
 }
}
```

4.4 Integer Optimization

An optimization problem where one or more of the variables are constrained to integer values is denoted an integer optimization problem.

Section 4.4.2 shows how to input an initial feasible solution to help the solver.

4.4.1 Example MILO1

In this section the example

maximize
$$x_0 + 0.64x_1$$

subject to $50x_0 + 31x_1 \le 250$,
 $3x_0 - 2x_1 \ge -4$,
 $x_0, x_1 \ge 0$ and integer (4.5)

is used to demonstrate how to solve a problem with integer variables.

The example (4.5) is almost identical to a linear optimization problem (see 4.1) except for some variables being integer constrained. Therefore, only the specification of the integer constraints requires something new compared to the linear optimization problem discussed previously.

The complete source for the example is listed in Listing 4.4.

Listing 4.4: How to solve problem (4.5).

```
using System;
using mosek.fusion;
namespace mosek.fusion.example
 public class milo1
 {
   public static void Main(string[] args)
      double[][] A =
        { new double[] { 50.0, 31.0 },
         new double[] { 3.0, -2.0 } };
      double[] c = { 1.0, 0.64 };
      using (Model M = new Model("milo1"))
      {
        Variable x = M.Variable("x", 2, Domain.Integral(Domain.GreaterThan(0.0)));
        // Create the constraints
               50.0 \ x[0] + 31.0 \ x[1] <= 250.0
                3.0 x[0] - 2.0 x[1] >= -4.0
        M.Constraint("c1", Expr.Dot(A[0], x), Domain.LessThan(250.0));
        M.Constraint("c2", Expr.Dot(A[1], x), Domain.GreaterThan(-4.0));
        // Set max solution time
        M.SetSolverParam("mioMaxTime", 60.0);
        // Set max relative gap (to its default value)
       M.SetSolverParam("mioTolRelGap", 1e-4);
        // Set max absolute gap (to its default value)
        M.SetSolverParam("mioTolAbsGap", 0.0);
        // Set the objective function to (c^T * x)
        M.Objective("obj", ObjectiveSense.Maximize, Expr.Dot(c, x));
        // Solve the problem
        M.Solve();
        // Get the solution values
        double[] sol = x.Level();
        Console.WriteLine("x1,x2 = \{0\}, \{1\}", sol[0], sol[1]);
        double miorelgap = M.GetSolverDoubleInfo("mioObjRelGap");
        double mioabsgap = M.GetSolverDoubleInfo("mioObjAbsGap");
        Console.WriteLine("MIP rel gap = {0} ({0})", miorelgap, mioabsgap);
   }
 }
}
```

4.4.2 Specifying an initial solution

Integer optimization problems are generally hard to solve, but the solution time can often be reduced by providing an initial solution for the solver. It is not necessary to specify the whole solution. By setting the <code>mioConstructSol</code> parameter to on and inputting values for the integer variables only, will force **MOSEK** to compute the remaining continuous variable values.

If the specified integer solution is infeasible or incomplete, MOSEK will simply ignore it.

Consider the problem

maximize
$$7x_0 + 10x_1 + x_2 + 5x_3$$
 subject to
$$x_0 + x_1 + x_2 + x_3 \le 2.5$$

$$x_0, x_1, x_2 \in \mathbb{Z}$$

$$x_0, x_1, x_2, x_3 \ge 0$$

$$(4.6)$$

The following example demonstrates how to optimize the problem using a feasible starting solution generated by selecting the integer values as $x = \{0, 2, 0, 1\}$ by the method Variable.setLevel.

The fundamental step is to feed **MOSEK** with the putative (feasible) solution: this is doe using the *Variable.setLevel* method, as reported in Listing 4.5.

Listing 4.5: Fusion implementation of problem (4.6) specifying an initial solution.

```
x.SetLevel( init_sol );
```

The complete code follows in Listing 4.6.

Listing 4.6: Fusion implementation of problem (4.6) specifying an initial solution.

```
using System;
using mosek.fusion;
namespace mosek.fusion.example
 public class mioinitsol
 {
   public static void Main(string[] args)
      double[] c = { 7.0, 10.0, 1.0, 5.0 };
      double[] init_sol = { 0.0, 2.0, 0.0, 1.0 };
      int n = 4;
      using (Model M = new Model("mioinitsol"))
        Variable x = M.Variable("x", n, Domain.Integral(Domain.GreaterThan(0.0)));
        // Create the constraint
        M.Constraint(Expr.Sum(x), Domain.LessThan(2.5));
        // Set max solution time
        M.SetSolverParam("mioMaxTime", 60.0);
        // Set max relative gap (to its default value)
        M.SetSolverParam("mioTolRelGap", 1e-4);
        // Set max absolute gap (to its default value)
        M.SetSolverParam("mioTolAbsGap", 0.0);
        // Set the objective function to (c^T * x)
        M.Objective("obj", ObjectiveSense.Maximize, Expr.Dot(c, x));
        x.SetLevel( init_sol );
        // Solve the problem
        M.Solve();
        // Get the solution values
        double[] sol = x.Level();
        Console.Write("x = [");
        for(int i=0;i<n;i++)</pre>
          Console.Write("{0}, ",sol[i]);
        Console.WriteLine("]");
```

```
double miorelgap = M.GetSolverDoubleInfo("mioObjRelGap");
    double mioabsgap = M.GetSolverDoubleInfo("mioObjAbsGap");
    Console.WriteLine("MIP rel gap = {0} ({0})", miorelgap, mioabsgap);
}
}
}
```

DESIGN PRINCIPLES

Fusion has been designed based on many year of experience on Conic Optimization Problem. We believe that a dedicated API for conic optimization can be valuable to many **MOSEK** users that regularly solve Conic Optimization Problems and want to enjoy a simpler experience interfacing with the solver.

What Fusion is

An object-oriented framework for conic-optimization.

What Fusion is not

A modeling language.

Fusion is design for a fast and clean prototyping of Conic Optimization Problem, helping users in set and run problems quickly. At the same time users should not suffer excessive performance degradation.

Fusion has been design with the following ideas in mind:

- Expressiveness: we try to make it nice! Despite not being a modeling language, Fusion yields a pretty readable code that users mainteining and sharing their work.
- Seamlessly multi-language: Fusion users should be able to port Fusion based code across different supported languages with almost no modifications, except for those dependent on the languages themselves.
- What you write is what ** |mosek| **gets: Fusion do not perform any black-magic behind the scene! The model is feed into the solver with (almost) no additional transformations.

In the next section we elaborate on this topics.

5.1 A Seamless Multi-language API

Fusion has been designed to allow users to port their code easily across the supported programming languages. This means that all functionalities and naming conventions are the same, no matter what is the language.

The main purposes of this design choice are:

- To make easier to share code among people using different languages In some settings people work together but like to use different languages.
- To improve code reusability Code written in certain language may be needed in the future for other projects that use a different language.
- To ease transition from R & D to production It is often easier to use fast-prototyping languages (as Python or MATLAB) during R & D, but production may required a different language, not least for performance sake.

As an example, let's see how a non-negative variable is declared in the supported languages:

Python

```
x = M.variable('x',1,Domain.greaterThan(0.))
```

Java

```
Variable x= M.variable("x", 1, Domain.greaterThan(0.));
```

C++

```
auto x= M->variable("x", 1, Domain::greaterThan(0.));
```

.NET

```
Variable x= M.Variable("x", 1, Domain.GreaterThan(0.0));
```

MATLAB

```
x= M.variable('x',1, Domain.greaterThan(0.));
```

The only significant differences are language related, i.e. they do not depends on Fusion. A careful coding can minimize such differences and improve even further the cross-language portability. Designing an interface spanning different programming languages is quite a challenge and leads to some limitations, as reported in Section 3.1.1.

5.2 What You Write is What MOSEK Gets

Many object-oriented optimization frameworks allows a great flexibility of usage and they often support several solvers. The price to pay is that the model, as defined by the user, must be transformed in the formulation required by the solver. The framework may also perform some preprocessing autonomously (for instance scaling or conic reformulation). As result, the model formulated by the user may **not** be what the solver gets.

Fusion follows a different approach:

- 1. it clearly defines the formulation that the user must adhere to,
- 2. it only provides those functionalities required for that formulation,
- 3. it only performs transformations that involves additional variables required to correctly formulate conic constraints.

The only transformation that Fusion performs is the following: for each conic constraint of the form

$$Ax + b \in \mathcal{K} \tag{5.1}$$

with $A \in \mathbb{R}^{m \times n}$, $x \in \mathbb{R}^n$, a vector of variables $y \in \mathbb{R}^m$ is introduced along with linear constraints, so that (5.1) is reformulated as

$$y = Ax + b$$

$$y \in \mathcal{K}$$

$$(5.2)$$

This mapping is necessary to ensure that each variable only belongs to one cone. Users accessing **MOSEK** through the low-level **MOSEK** Optimizer API for .NET are required to make the mapping themselves. So *Fusion* does not make any transformation that the user would not have done himself.

Let's make an example: we want to define a constraint of the form

$$x_1 \ge \sqrt{(2x_2)^2 + (4x_3)^2}$$

which in conic form corresponds to

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \in Q \tag{5.3}$$

To bring equation (5.3) in the standard conic form accepted by the solver, we need to introduce additional variables y_i such that

- 1. each variable belongs to a single cone,
- 2. the cone can be formulated as $x_0 \ge \sqrt{\sum x_i^2}$.

Thus the user is forced to transform the constraint in the form

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = y,$$

$$y \in Q$$
(5.4)

The user can decide to make this kind of transformation himself, or let *Fusion* automatized the process. The results will be the same. To summarize:

- Fusion only allows user to define Conic Optimization Problem whose form is that of Problem (5.1).
- The only transformation performed by Fusion is the introduction of auxiliary variables.
- Any other problem pre-solving and transformation are left to MOSEK.

The main benefits of this approach are:

- 1. The user knows what is the problem that the solver is actually solving.
- 2. Dual informations are readily available.
- 3. Reduced overhead.
- 4. Better control over numerical issues: scaling and other transformation may introduce numerical instability hard to detect.

CONIC OPTIMIZATION MODELING

The main purpose of Fusion is to provide a simple and intuitive modeling API for conic linear optimization. A Conic Optimization Problem can be formulated compactly as

minimize_{$$x \in \mathbb{R}^n$$} $c^T x$
 $s.t.$ $A_i x + b_i \in \mathcal{K}_i$ $i = 1, ..., m$ (6.1)

where $K_i \in \mathcal{D} = \{\mathbb{R}_+, \mathcal{Q}, \mathcal{Q}_r, \mathcal{S}_+\}$. Fusion extends \mathcal{D} considering also some handy set defined by linear constraints:

- ranged variable: $\mathcal{R}^n = \{x \in \mathbb{R}^n | l \le x \ge u\}$
- upper bounded variable: $U^n = \{x \in \mathbb{R}^n | x \ge u\}$
- lower bounded variable: $\mathcal{L}^n = \{x \in \mathbb{R}^n | l \le x\}$
- unbounded variable: \mathbb{R}^n

Then cone Fusion accepts cones such as $K_i \in \mathcal{D} \cup \{\mathcal{R}, \mathcal{U}, \mathcal{L}, \mathbb{R}\}.$

The building blocks of a Conic Optimization Problem are

- Variables
- Linear operators
- Domains

Combining variables and linear operators we obtain affine functions that we can use to define the objective function and the constraint of our model.

- Objective Function we ask to minimize of maximize the affine function, see Section 6.7.
- Constraints we ask that the image of affine function must belong to a given domain.

To create linear expression also matrices and vectors are needed. *Fusion* accepts plain arrays or matrices. However, it also provides simple classes to represent *dense and sparse matrices*.

Moreover, variables and epressions can be manipulated (stacking, reshaping or slicing) creating logical views.

Warning: A model built using Fusion is always a Conic Optimization Problem.

6.1 Optimization Model

The optimization model is the object that contains all information that define an conic optimization model:

$$\min_{s.t.} c^T x$$

$$s.t.$$

$$Ax + b \in \mathcal{K}$$

It is represented by the class Model and it is responsible for

- creating all the items define the optimization problem, i.e. variables, contraints and objective function;
- interface with the solver (see Section 8).

This is particularly convenient because the user mainly interact with this class and, more importantly, leads to a safe and simple memory management. To create an optimization model, simply write

```
using (Model M = new Model())
{
```

The name is optional. The returned object is what the user interacts with. It is important to keep in mind that

Important: A model owns all entities that it creates and it is responsible for their destruction.

As a consequence each model component can not be shared among models. There may be multiple models active at the same time.

Through an optimization model users can specify all the relevant component of an optimization model such

- Variables
- Constraints
- Objective function

All these elements must be created using the corresponding methods in Model, i.e. Model.variable, Model.constraint and Model.objective, respectively.

The Model is also the primary interface between the user and the solver (see Section 8). For this reason it provides methods for

- set up parameters (see Section 8.1)
- \bullet access problem and solution status (see Section 8.2)
- perform I/O operations (see Section 8.3)

Note: For those users familiar with the **MOSEK** Optimizer API: a *Model* instance is a wrapper on top of the problem task.

6.2 Matrices

Fusion provides a minimal support for matrix representation. The main purposes are

- 1. to provide the user with a convenient storage when the native language does not provide any,
- 2. to give the user the possibility to write a cross-platform code,
- 3. allow for a generic code in which sparse and dense matrices can be use with no modifications.

However, *Fusion* is **not** focused on providing matrix operations or any kind of linear algebra routines. The user should use specialized packages available for the programming language of interest.

Matrices in *Fusion* are stored either in *dense* or *sparse* format. Despite specific implementation are provided, the user is only supposed to interact with the generic interface *Matrix*. Matrices must be created by means of the static methods

• Matrix. dense for dense matrices,

• Matrix. sparse for sparse matrices.

Note: Fusion does not detect sparsity automatically.

A Matrix object is unmutable and therefore cannot be modified.

6.2.1 Dense Matrices

Dense matrices are the choice when the number of non zero entries is large. To specify a dense matrix one must use the <code>Matrix.dense</code> static method.

A dense matrix is specified providing its dimensions and the values that contains. It can not be left unspecified. Therefore the user must provide one of the following

• a common value for all entries: for instance

$$A = \left[\begin{array}{rrrr} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{array} \right]$$

one may write the following code:

```
int n = 4;
Matrix ones= Matrix.Ones(n,n);
```

A matrix with all entries equal to one can also be created by Matrix. ones.

• a complete set of values by a native representation, as for instance

$$A = \left[\begin{array}{rrrr} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{array} \right]$$

one may write the following code:

```
double[,] A= new double[,]{ {1.0,2.0,3.0,4.0}, {5.0,6.0,7.0,8.0} };
Matrix Ad= Matrix.Dense(A);
```

• a flattened representation, i.e. all values stored in a one-dimensional array. For instance, the to declare

$$A = \left[\begin{array}{rrrr} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{array} \right]$$

one may write the following code:

```
double[] Af={ 1,2,3,4,5,6,7,8 };
Matrix Aff= Matrix.Dense(2,4,Af);
```

The matrix is built row-wise.

6.2.2 Sparse Matrices

When the number of non zero elements is relatively small, then a sparse matrix is a preferable choice. It only stores the non zero elements in triplet form, i.e. each entry is represented by a triplet (i,j,v) where

- i is the row
- j is the column
- v is the non zero value

6.2. Matrices 29

The order of the triplets is not relevant. To specify a sparse matrix one must use the <code>Matrix.sparse</code> static method.

For instance, the representation of

$$A = \left[\begin{array}{cccc} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 \end{array} \right]$$

in triplet form is

$$A = \{(0,0,1), (0,3,1), (1,1,1), (1,3,1)\}$$

where we use the convention of 0-based indexes. In Fusion this corresponds to:

```
int[] rows = { 0, 0, 1, 1 };
int[] cols = { 0, 3, 1, 2 };
double[] values= { 1.0, 1.0, 1.0, 1.0 };

Matrix ms= Matrix.Sparse(rows.Length, cols.Length, rows, cols, values);
```

Runnig the code will result in the following output

```
SparseMatrix(2,4, (0,0,1.0),(0,3,1.0),(1,1,1.0),(1,2,1.0))
```

Fusion provides also helper functions to create some of the most used sparse matrices:

- a diagonal matrix can be created simply by the Matrix. diag method;
- the identity matrix of size n can be created using the Matrix.eye method. It is a short-hand for the diagonal matrix.

6.2.3 Block Matrices

Many problems are characterized by linear expressions whose coefficient matrix has a block structure. *Fusion* allows to input block diagonal matrices, i.e.

$$M = \left[\begin{array}{ccc} A & 0 & 0 \\ 0 & B & 0 \\ 0 & 0 & C \end{array} \right],$$

where A, B and C may have different dimensions. Using the method Matrix.diaq we can write

$$M = \left[\begin{array}{cc} I_2 & 0 \\ 0 & 2I_3 \end{array} \right],$$

with I_k being the identity matrix of dimension k, as

```
Console.WriteLine( Matrix.Diag( new Matrix[]{Matrix.Eye(2),Matrix.Diag(3,2.0)}).ToString());
```

The output is

```
'SparseMatrix(5,5, [(0,0,1.0),(1,1,1.0),(2,2,2.0),(3,3,2.0),(4,4,2.0)])'
```

See Matrix.diag for details.

6.3 Domains

A domain specifies the set in which a linear expression must belong to. In particular, as explained in Section 6.5, the feasible set of a conic optimization problem is defined by a set of constraints of the form:

$$A_i x + b_i \in \mathcal{K}_i, \quad i = 1, \dots, m$$

for suitable matrices A_i and vectors b_i . Each constraint represents the intersection of a cone with a affine set generated by the linear expression. For sake of simplicity we will focus instead on the expression

$$y \in \mathcal{K}$$
.

MOSEK solves conic optimization problems involving the fundamental symmetric cones:

- 1. positive orthant: $\mathbb{R}^n_+ = \{x \in \mathbb{R}^n | x \ge 0\}$
- 2. Lorentz cone: $Q^{1+n} = \{(y, x) \in \mathbb{R}^{1+n} | y \ge ||x||_2 \}$
- 3. Rotated cone: $Q_r^{2+n} = \{(y, w, x) \in \mathbb{R}^{1+n} | 2yw \ge ||x||_2, w \ge 0, y \ge 0\}$
- 4. PSD matrices: $S_{+}^{n} = \{X \in S^{n} | y^{T} X y \geq 0 \quad \forall y \in \mathbb{R}^{n} \}$

With these fundamental cones we can describe all constraints supported by MOSEK.

Domains are represented by specific classes. To declare a domain, we use the corresponding static method in *Domain*, as listed in the following table.

	Name	class method
	unboundness	Domain.unbounded
Linear	equality	Domain.equalsTo
Linear	inequality \leq	Domain.lessThan
	inequality \geq	${\it Domain.greaterThan}$
Quadratic	Lorentz cone	Domain.inQCone
Quadratic	Rotated Lorentz cone	${\it Domain.inRotatedQCone}$
	PSD matrix	Domain.inPSDCone
Symm. Matr.	linear PSD matrix	Domain.isLinPSD
	tri-linear PSD matrix	Domain.isTrilPSD

Warning: If no domain is specified for a variable, then the variable is left unconstrained!

6.3.1 Linear Domains

Linear domains are based on the positive orthant cone

$$\mathbb{R}_{+} = \left\{ x \in \mathbb{R} | x \ge 0 \right\},\,$$

combined with an affine transformation x = ay + b. That allows to define other useful and commonly used domains:

- $x \ge b$ setting a = 1 (Domain. greaterThan),
- x < b setting a = -1 (Domain.lessThan),

 $Fusion \ {\it also contemplates explicitly unboundeness by } {\it Domain.unbounded} \, .$

6.3.2 Quadratic Cones

Both

- Lorentz cone: $Q^{1+n} = \{(y, x) \in \mathbb{R}^{1+n} | y \ge ||x||_2\}$ and
- Rotated cone: $Q_r^{2+n} = \{(y, w, x) \in \mathbb{R}^{1+n} | 2yw \ge ||x||_2, w \ge 0, y \ge 0\}$

are available using the *Domain.inQCone* and *Domain.inRotatedQCone* static methods, respectively. It must be understood that it is possible to express one cone in terms of the other bby means of an orthogonal transformation. That means one of the two cone is somehow redundant, but often very useful fro ma modeling perspective. For instance, if we want to express a contraint like

$$||x||_2 \leq k$$

6.3. Domains 31

then the Lorentz cone exactly matches this constraint definition. But on the other hand,

$$x^T F F^T x = ||Fx||^2 \le k$$

can be easily expressed by a rotated cone as

$$y = Fx, \left(\frac{1}{2}, k, y\right) \in \mathcal{Q}_r$$

Tip: Try to use the cone that closely match the problem definition!

6.3.3 Semidefinite Matrices

In Fusion there are three different domains derived from the cone of the semidefinite matrices.

Warning: None of the following domains explicitly enforce symmetry!

Symmetrized PSD

Given a matrix $X \in \mathbb{R}^{n \times n}$ the domain imposes the constraint

$$\frac{1}{2}(X + X^T) \in \mathcal{S}^n_+$$

This is available using the Domain. in PSDCone.

Lower Triangular PSD Domain

Given a matrix $X \in \mathbb{R}^{n \times n}$ the domain imposes the constraint

$$Y_{ij} = X_{ij} \quad i \ge j$$
$$Y \in \mathcal{S}^n_+$$

This is available using the <code>Domain.isTrilPSD</code>.

Warning: The upper triangular part of X is left unspecified!

Linearized PSD Domain

6.3.4 Domain Size and Dimensions

Each domain has an intrinsic number of dimenions and minimum size, listed in table Table 6.3.4.

Domain	Dimensions	Minimum size
Linear	0	1
Lorentz cone	1	2
Rotated Cone	1	3
Symm. Matr.	2	1

The size and number of dimensions of a domain must match those of the object it must contains. However the size of a domain may or may not be fully specified: this gives *Fusion* the freedom to adapt the domain in order to match the dimension of the corresponding variable/constraint. If it is not possible an exception *FusionException* is thrown. See Section 6.5.

6.3.5 Integral Domains

For all domains, except those involving semidefinite matrices, the method *Domain.integral* can be used to restrict a given domain only to the integer values it contains. Therefore the specifier *Domain.integral* can only be used in combination to other domains. For instance, to declare a single integer variable $z \in [1, 10]$ we may write:

```
Variable z = M.Variable("z", Domain.Integral(Domain.InRange(1.0,10.0)) );
```

Notice that binary variables are a special case of integer variables, and therefore to declare a binary variable \mathbf{x} we may write

```
Variable x = M.Variable("x", Domain.Integral( Domain.InRange(0.0,1.0) ));
```

A handy specialized domain is provided by the *Domain. binary* function. For example, a binary variable $y \in \{0,1\}^n$ can be declared as

```
Variable y = M.Variable("y", Domain.Binary());
```

Integrality can also be forced or relaxed after a variable has been created by means of the method <code>Variable.makeContinuous</code> and <code>Variable.makeInteger</code>.

6.4 Variables

In Fusion variables are objects that represent n-dimensional arrays. The base class Variable is the main interface the user works with.

Variables are declared using the *Model.variable* method that returns an object of type *Variable* representing the variable itself.

Important:

- a variable belongs to the model it is constructed by,
- the variable dimension and shape are immutable.

On the other hand, reshaped views can be easily obtained (see Section 6.8).

The information that characterize a variable are:

- the variable shape and dimensions;
- the domain it must belong to using a domain specifier class of type Domain (see Section 6.3).
- an optional name.

For instance, to declare a non-negative one-dimensional variable x of length n we may write

```
Variable x = M.Variable("x",n, Domain.GreaterThan(0.0));
```

A multidimensional array is declared simply specifying an array with all dimension sizes. For instance, a bi-dimensional $n \times n$ matrix of unbounded variables x can be declared as

```
Variable x = M.Variable( new int[]{n,n}, Domain.Unbounded() );
```

Many other combinations of parameters are available and allow to declare also semidefinte matrices and integer variables (see Section 6.4.1). All variant return an implementation of the *Variable* base class. This type of object is a placeholder that can be used to

• form linear expressions and define constraints (see 6.5),

6.4. Variables 33

• check the problem and solution status, along with the returned primal and dual values, after the optimization (see 8.2).

6.4.1 Integer Variables

Integer variables are expressed in the same way as the continuous, but with an additional domain specification to force integrality. Fusion will consider all integers in the specified domain. To add an integer variable $z \in [1, 10]$ we write

```
Variable z = M.Variable("z", Domain.Integral(Domain.InRange(1.0,10.0)) );
```

Binary variables are declared either as

```
Variable x = M.Variable("x", Domain.Integral( Domain.InRange(0.0,1.0) ));
```

or with the helper function Domain.binary

```
Variable y = M.Variable("y", Domain.Binary());
```

Warning: The interval limits must be real numbers.

In addition, integrality can be relaxed or enforced using the switch methods Variable.makeContinuous and Variable.makeInteger.

6.4.2 Views

It is often convenient to access a subset of a variable elements, to combine two or more variables or to reorganize a multidimensional variable in a different shape. For this reason *Fusion* provides a set of functions that return a *view* of the original variables..

In all cased the returned object still refers to the original one. It is just a logical placeholder. In the next subsections we will give some more details. For more details please refer to Section 6.8.

Reshaping

It keeps the same overall size but different number of dimension or their length. If the new shape is not compatible with the original size, an exception of type DimensionError is thrown. Available functions include

Function	Description
Var.reshape	General reshaping
Var.flatten	Returns a one dimensional representation
Var.compress	Remove all redundant dimensions of length one

Vector and matrix variables can also be transpose by Variable. transpose.

Slicing

It selects a subset of a variable element. Selection can be performed in different ways, the most common one being listed in the following table:

Function	Description
Variable.slice	select contiguous subsets
Variable.pick	select elements by set of indexes
Variable.index	select a single element by index

It is also possible to extract the diagonal of a two dimensional squared variable using the <code>Variable.diag</code> function.

Stacking

It returns a logical view that merges several variables in a single one. Stacking is useful to combine different variables in order to write a more compact set of contraints. We distinguish among three stacking operations, as in the following table

Function	Description
Var.hstack	concatenate along the first dimension
Var. vstack	concatenate along the second dimension
Var.stack	general block stacking

It is important to stress that the returned variable is only a view of the original ones. For more details, please refer to Section 6.8.

6.4.3 Variable Naming

As stated in Section 6.4, an optional name can be specified for each variable. This is particularly useful when debugging or storing a model, or reporting results. Names must be specified when variables are declared and cannot be changed afterwards. Variable indices are automatically generated.

When saving a model to file, *Fusion* will also include all the auxiliary variables that has been generated during the model building phase. The naming of these variables follows the following rules:

A careful choice of meaningful names can be of great help. Fusion puts no limitations on the names but the following rules apply:

- 1. names must be unique for the model the variable belongs to;
- 2. the value *None is* allowed and correspond to automatic names;
- 3. they must not collide with automatically generated names.

6.4.4 Pretty Printing

Variable information can be printed out in a human-readable form using the method <code>Variable.toString</code>. The text contains

- type,
- name and
- dimension.

The textual representation is generated as compact as possible. For instance a one dimensional variable called x will be printed just saying

```
int n = 4;
Variable x = M.Variable("x",n, Domain.GreaterThan(0.0));
Console.WriteLine( x.ToString() );
```

with the following output

```
LinearVariable(('x',4))
```

Notice that if no names are assigned an empty string will be used instead, i.e. no automatic names are generated.

6.4. Variables 35

6.5 Linear Expressions

In Fusion linear expressions are constructed combining variables and matrices by linear operators. The result is an object that represent the linear expression itself.

Important: Fusion only allows for those combinations of operators and arguments that yields linear functions.

For instance the dot product between two vector of variables is not allowed, as it yields a quadratic function. As a consequence, at most one of the arguments of the expression can be a variable.

For a given expression, we define as

- dimension the dimension of the result of the expression,
- size the product of the expression dimension times the input dimension.

For instance, given $x \in \mathbb{R}^n$ and $A \in \mathbb{R}^{m \times n}$, the dimension of Ax is m and its size is nm.

Linear expressions are used to define the constraints and the objective function.

6.5.1 Storing Expressions

Expressions are concrete implementations of the virtual interface *Expression*.

Note: Typically one never needs to directly use *Expression* and its descendants.

Expressions are organized in matrices, and therefore they inherit the possibility to be sliced, reshaped and stacked. These operations could be useful in practice and yield very compact formulations. For instance, if we want to express

$$Ax_i = b_i$$
 $i = 1, \ldots, n$

we can think of $x_i \in \mathbb{R}^m$ as the column of a matrix and therefore write simply

$$AX = B$$
, $X = [x_1 \dots x_n]$, $B = [b_1 \dots b_n]$.

The resulting expression AX has dimension $n \times m$, i.e. is a matrix expression.

6.5.2 Defining Expressions

Linear operators are provided as static method by the Expr class. Each operator returns an expression object of type Expression.

Fusion currently support the linear operators listed in Table 6.1.

Table 6.1: Linear Operators

Method	Description
Expr. add	Element-wise addition of two matrices
Expr. sub	Element-wise subtraction of two matrices
Expr.mul	Matrix multiplication
Expr.neg	Sign inversion
Expr.outer	Vector outer-product
$\mathit{Expr.dot}$	Dot product
Expr.sum	Sum over a given dimension
Expr.mulDiag	Sum over the diagonal of a matrix which is the result of a matrix multiplication
Expr.constTerm	Return a constant term

Note that some of the operators are provided for user convinence, as they could be obtained by means of others. Please click on te corresponding link to see more details.

Dimensionality checking

Fusion perform dimensionality checking on the arguments of a linear operators: an exception of type DimensionError will be thrown if errors are detected.

Composing expressions

Expression can be composed and nested. This allow to define more complex expressions: for instance say we want to write

$$Ax + By$$
,

for appropriate matrices A, B and variables x, y. The code will look like:

```
Expr.Add( Expr.Mul(A,x), Expr.Mul(B,y) );
```

Given that expressions can be stored, one can also define expression separately and then combine them:

```
Expression Ax = Expr.Mul(A,x);
Expression By = Expr.Mul(B,y);

Expression add = Expr.Add(Ax,By);
```

Composition is pretty useful, but it may lead to unreadable code. Users should also consider using list-based expressions if possible. To write an expression such as

$$x + y + z + w$$

where x, y, z, w are all vectors of variables of the same size, a first option is

```
Expr.Add(x, Expr.Add(y, Expr.Add(z,w) ) );
```

which is not very much readable. A cleaner way can be to store all terms in a list, for instance

```
Expr.Add( new Variable[]{x, y, z, w});
```

Similar function are provided for other expressions.

6.6 Constraints

A constraint in Fusion must have the form

$$l(x) \in F$$

where l(x) is an affine function (see section 6.5), and F must be a domain among those provided by Fusion (see Section 6.3).

A constraint is characterized by its

- \bullet type
- size
- number of dimensions of the image of l(x),

6.6. Constraints 37

• number of non-zeros entries are the actual number of terms that defines the affine function. This is one of the most important measure of the actual dimension of a Conic Optimization Problem.

For instance, the following set of linear constraints

$$\begin{array}{rcl}
x_1 & + & 2x_2 & = 0 \\
 & + & x_2 & + & x_3 & = 0 \\
x_1 & & = 0
\end{array} \tag{6.2}$$

has size three, number of dimensions equals to one (the image is indeed a one dimensional array) and five non zero elements.

The dimensions of F and l(x) must match, otherwise an error is reported. To this end Fusion tries to smartly deduce the dimension of F, whenever possible and safe, to that of l(x).

6.6.1 Contraint Declaration

Constraints must be created using the static method Model.constraint. A constraint is defined by three parameters:

- 1. An optional name: it is useful for debugging purposes or when dumping the model to file. However, it may introduce a significant overhead for large models.
- 2. A linear expression
- 3. The domain of the image of the linear expression

The Model.constraint method returns a Constraint object that can be used by the user to access constraint information, see Section Constraint Information.

For instance, the set of linear constraints (6.2) can be declared as

6.6.2 Constraint Information

There are several information that can be obtained from a costraint object.

The size and number of number of dimensions are available using the methods Constraint.size and $Constraint.get_nd$.

It is also possible to recover dual information using the method Constraint. dual.

Warning: Dual information are only available for continuous problems and if a (near) optimal solution has been found!

6.6.3 Pretty Printing

A human readable representation of the constraint can be obtain using the *Constraint.toString* method.

The representation of a *Constraint* instance is the list of all contained constraints. For instance a set of linear constraints of the form Ix = 0, with I being the identity matrix is implemented as

```
int n = 4;
Variable x = M.Variable("x",n, Domain.GreaterThan(0.0));
Constraint c = M.Constraint("c", Expr.Mul(Matrix.Eye(n),x), Domain.EqualsTo(0.0));
Console.WriteLine(c.ToString());
```

The output is

```
Constraint('c', (4),
c[0]: + 1.0 x[0] = 0.0,
c[1]: + 1.0 x[1] = 0.0,
c[2]: + 1.0 x[2] = 0.0,
c[3]: + 1.0 x[3] = 0.0)
```

Notice that only non zero entries are printed.

The printed representation also includes all auxiliary variables introduced by Fusion. For instance a single second order cone of the form

$$(t,x) \in \mathcal{Q}$$

with $t \in \mathbb{R}, x \in \mathbb{R}^n$, implemented as

```
int n = 4;

Variable x = M.Variable("x", n, Domain.GreaterThan(0.0));

Variable t = M.Variable("t", 1, Domain.GreaterThan(0.0));

Constraint c = M.Constraint( Expr.Vstack(t,x), Domain.InQCone());

Console.WriteLine( c.ToString() );
```

it will produce

This method is particulary useful when the model must be inspected for debugging. However it must be notice that

- when the number of variable involved in the constraint is large, it may generate a large amount of output as well;
- meaningful names must be provided for the relevant variables.

```
Warning: If no names are given, Fusion will just display empty strings!
```

6.7 Objective Function

In Fusion the objective function must be an affine function of size one, i.e. returning a scalar, otherwise an exception of type DimensionError is thrown.

The optimization sense can be either minimize or maximize and

Note: in *Fusion* the optimization sense must always be specified.

The only exception is the trivial case in which the objective function is a constant term.

The objective function is declared using the static method Model.objective. It requires:

- the optimization sense from the enumeration ObjectiveSense,
- the linear expression defining the objective function and an optional name, see Section 6.5.

For instance, to minimize a variable t we will write

```
Variable t = M.Variable("t", 1, Domain.Unbounded() );
M.Objective( ObjectiveSense.Minimize, t);
```

The typical linear objective function $c^T x$ can be declared as

```
double[] c = new double[] {1.0, 1.0, 1.0};
int n = c.Length;
Variable x = M.Variable("x", n, Domain.GreaterThan(0.0));
M.Objective( ObjectiveSense.Minimize, Expr.Mul(c,x));
```

Note that the objective function is a little peculiar in *Fusion*:

- it is the only component of an optimization model that can not be stored and reused,
- it cannot be modified,
- it can be overwritten.

6.7.1 Changing the Objective Function

The objective function can be overwritten at any time. This is particularly useful when solving a sequence of problems in which only the objective function varies. For instance, if we want to minimize the following linear function

$$f(x) = \gamma x + \beta y,$$

where $\gamma, \beta, x, y \in \mathbb{R}$, for different values of the parameter $\gamma > 0$. The function is trivial, but it conveys the overall ideas. We may use the following code:

```
double[] gamma= new double[] {0.0, 0.5, 1.0};
double beta = 2.0;

Variable x= M.Variable("x", 1, Domain.GreaterThan(0.0));
Variable y= M.Variable("y", 1, Domain.GreaterThan(0.0));

Expression beta_y = Expr.Mul(beta,y);
for(int i=0;i<3;i++)
{
    M.Objective( ObjectiveSense.Minimize, Expr.Add(Expr.Mul(gamma[i],x), beta_y));
    M.Solve();
}</pre>
```

This is particularly useful when performing for instance multi/objective optimization.

Tip: Notice how the common expression can be stored and reused.

6.8 Variable and Expression Views

In Fusion variables and expressions are organized as multi-dimensional objects. We will refer in general to matrix-like object, or more simply to a matrix meaning both variables and expressions.

Matrix-like objects are characterized by a **shape** that accounts for the dimension of the space in which the object lives in. The shape is represented by an array of integers such that

- the length is the **dimension** on the matrix,
- each entry is the size along that dimension and
- \bullet the product of all dimensions is the ${\bf size}$ of the matrix.

For instance the matrix

$$A = \left[\begin{array}{ccc} 1 & 2 & 3 \\ 4 & 5 & 6 \end{array} \right]$$

has shape $\{2,3\}$, dimension 2 and size $2 \times 3 = 6$.

The shape is an intrinsic property that is **immutable** in *Fusion*, and can be obtain by the methods *Variable.getShape* and *Expression.getShape*.

It is often useful to

- re-organize matrix elements in a different way, i.e. reshaping,
- only consider a subset of elements, i.e. picking and slicing and
- pack matrices together, i.e stacking.

All these operations do not require *new* variables or expressions, but just logical **views**. Fusion provides an unified set of methods to creates views for variables and expressions. It is must be stressed that

Important: A views does not introduce neither new variables nor additional constraints. In general it is a lightweight object that only requires a small amount of memory.

6.8.1 Reshaping

Reshaping a matrix means to rearrange its elements in a different shape, with the same size.

Flattening

This operation returns a **one-dimensional** representation of the matrix. The elements are listed traversing the matrix in row-wise order. For a two dimensional matrix $x \in \mathbb{R}^{n \times m}$ the result of the flatting operation is

$$[x_{11}, x_{12}, ..., x_{1m}, ..., x_{n1}, x_{n2}, ..., x_{nm}]$$

For instance the flattening of

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix} \tag{6.3}$$

is the following one-dimensional array f

$$f^{T} = \begin{bmatrix} 1 & 2 & 3 & 4 & 5 & 6 \end{bmatrix}^{T}. {(6.4)}$$

Flattening is available both for variables (see Var. flatten) and expressions (see Expr. flatten).

General Reshaping

It returns a view of the matrix with a different shape with the same size. The entries of the original matrix are mapped as follows:

- 1. first the matrix is *flattened* yielding an array f,
- 2. a new matrix with the new shape is created,
- 3. the new matrix is filled using f.

Note that in general the number of dimensions may differs. The only strict requirements is that the size must match.

For instances, let's assume we are given a matrix as follows

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}, \tag{6.5}$$

but we need to see it as a matrix with three rows and two columns. A is first flattened, as in (6.4) and then its values rolled over the new shape. The final result is

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \\ 5 & 6 \end{bmatrix}. \tag{6.6}$$

Flattening is available both for variables (see Var. reshape) and expresisons (see Expr. reshape).

6.8.2 Slicing and Picking

Sometimes constraints and objective function only involve a sub-set of variables. It is then useful to have a way to select them in a compact way.

- picking: it selesct a subset of possibly non-contiguous variable entries.
- slicing: it selects a continuous sebset of variable entries.

Clearly *slicing* is a special case of *picking*. However, *slicing* occours so frequently that deserve dedicated methods.

Picking

Picking is the operation of selecting elements based on a list of indexes. The resulting view is a one dimensional array.

For a given variable x, in the general case the user must provide a list L of indexes to identify the items and the resulting array p will be arranged such that:

$$p[i] = x[L[i]]$$

For instance, given a two dimensional matrix A of dimension $n \times n$

$$A = \left[\begin{array}{ccc} 1 & 2 & 3 \\ 4 & 5 & 6 \end{array} \right],$$

to select the upper-left and bottom-right item we specify a list that contains the coordinates of the elements, i.e

$$\{(0,0),(1,2)\}.$$

The result is the one-dimensional array $\{1,6\}$. If we specify

$$\{(1,2),(0,0)\}.$$

we obtain $\{6,1\}$.

Note how the element coordinates are tuples with the same dimension as the matrix.

Fusion provides several variant of the Variable.pick and Expression.pick methods. Single element access by the methods Variable.index and Expr. index is a special cases of picking.

Slicing

Slicing refers to the selection of a submatrix. A slice is defined by the range of indexes selected for each dimension: to select the elements in the range [first,last], we actually specify [first,last+1] = $[l_i, u_i]$. In this way the length of the slice along that dimension is exactly $[u_i-l_i]$.

Consider a matrix with shape 4×4 , as depicted in Fig. 6.1.

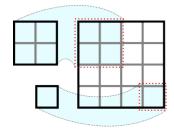

Fig. 6.1: Two dimensional slicing.

To select the upper-left 2×2 sub-matrix, we specify the range [0,2] for both dimensions; on the other hand, to select the cell on the bottom right corner, we use [3,4] again for both dimensions.

In Fusion slicing is obtained using the methods Variable.slice and Expression.slice, providing separate arrays for the starting and ending indexes. For instance, the previous example would require

- a first array [0,0] and a second [2,2] for the upper left corner,
- ullet a first array [3,3] and a second [4,4] for the lower right corner.

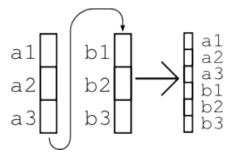

Fusion allows for slices in which dimensions can have zero length, i.e. where last equals to first. If last is less than first, an exception of type IndexError is thrown.

6.8.3 Stacking

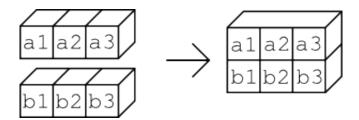

Stacking refers to the concatenation of matrices to form a new larger one.

Vertical Stacking

It concatenates matrices along the first dimension. In case of bi-dimensional matrices, they are put one on top of the other, i.e. vertically. For instance, given two column vectors a, b, i.e. with second dimension equals to one, the vertical stacking of a on top of b is depicted in the following figure.

On the other hand, if the second dimension is one, the results is the following

In Fusion this operation is performed by the Expr. vstack and Var. vstack functions.

Horizontal stacking

It concatenates matrices along the second dimension. In case of bi-dimensional matrices, they are put one beside the other, i.e. horizontally.

In Fusion this operation is performed by the Expr. hstack and Var. hstack functions.

Generalized stacking

It allows to combine several matrices as long as their dimensions match. For instance consider Fig. 6.2: five two-dimensional matrices must be combine to obtain a larger one.

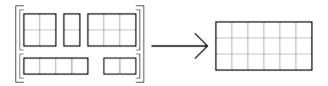

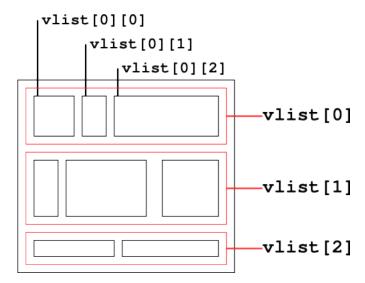

Fig. 6.2: An example of general stacking.

General stacking is supported for both variable (Var. stack) and expressions (Expr. stack).

Warning: Variables and expressions cannot mixed when stacking! You must promote variables to expressions using Variable.asExpr.

To better explain how stack works let's consider the case in Fig. 6.8.3

The matrices are stored in a two-dimensional array named vlist such that

- Each rows of vlist contains matrices with the same number of rows and
- Each rows has the same total number of columns.

If vlist is composed by variables, then we may write something along this line

CASE STUDIES

In this section we present some case studies in which the Fusion API for .NET is used to solve real-life applications. These examples involve some more advanced modeling skills and possibly some input data. The user is strongly recommended to first read the $basic\ tutorials$ before going through these advanced case studies.

7.1 Portfolio Optimization

This case studies is devoted to the Portfolio Optimization Problem.

7.1.1 The Basic Model

The classical Markowitz portfolio optimization problem considers investing in n stocks or assets held over a period of time. Let x_j denote the amount invested in asset j, and assume a stochastic model where the return of the assets is a random variable r with known mean

$$\mu = \mathbf{E}r$$

and covariance

$$\Sigma = \mathbf{E}(r - \mu)(r - \mu)^T.$$

The return of the investment is also a random variable $y = r^T x$ with mean (or expected return)

$$\mathbf{E}y = \mu^T x$$

and variance (or risk)

$$\mathbf{E}(y - \mathbf{E}y)^2 = x^T \Sigma x.$$

The problem facing the investor is to rebalance the portfolio to achieve a good compromise between risk and expected return, e.g., maximize the expected return subject to a budget constraint and an upper bound (denoted γ) on the tolerable risk. This leads to the optimization problem

$$\begin{array}{lll} \text{maximize} & \mu^T x \\ \text{subject to} & e^T x & = & w + e^T x^0, \\ & x^T \Sigma x & \leq & \gamma^2, \\ & x & \geq 0. \end{array} \tag{7.1}$$

The variables x denotes the investment i.e. x_j is the amount invested in asset j and x_j^0 is the initial holding of asset j. Finally, w is the initial amount of cash available.

A popular choice is $x^0 = 0$ and w = 1 because then x_j may be interpretated as the relative amount of the total portfolio that is invested in asset j.

Since e is the vector of all ones then

$$e^T x = \sum_{j=1}^n x_j$$

is the total investment. Clearly, the total amount invested must be equal to the initial wealth, which is

$$w + e^T x^0$$
.

This leads to the first constraint

$$e^T x = w + e^T x^0.$$

The second constraint

$$x^T \Sigma x < \gamma^2$$

ensures that the variance, or the risk, is bounded by the parameter γ^2 . Therefore, γ specifies an upper bound of the standard deviation the investor is willing to undertake. Finally, the constraint

$$x_j \ge 0$$

excludes the possibility of short-selling. This constraint can of course be excluded if short-selling is allowed.

The covariance matrix Σ is positive semidefinite by definition and therefore there exist a matrix G such that

$$\Sigma = GG^T. (7.2)$$

In general the choice of G is **not** unique and one possible choice of G is the Cholesky factorization of Σ . However, in many cases another choice is better for efficiency reasons as discussed in Section 7.1.2. For a given G we have that

$$\begin{array}{rcl} \boldsymbol{x}^T \boldsymbol{\Sigma} \boldsymbol{x} & = & \boldsymbol{x}^T \boldsymbol{G} \boldsymbol{G}^T \boldsymbol{x} \\ & = & \left\| \boldsymbol{G}^T \boldsymbol{x} \right\|^2. \end{array}$$

Hence, we may write the risk constraint as

$$\gamma \ge \left\|G^T x\right\|$$

or equivalently

$$[\gamma; G^T x] \in Q^{n+1}$$
.

where Q^{n+1} is the n+1 dimensional quadratic cone. Therefore, problem (7.1) can be written as

maximize
$$\mu^T x$$

subject to $e^T x = w + e^T x^0$,
 $[\gamma; G^T x] \in Q^{n+1}$,
 $x \geq 0$, (7.3)

which is a conic quadratic optimization problem that can easily be formulated and solved with *Fusion*. Subsequently we will use the example data

$$\mu = \left[\begin{array}{c} 0.1073 \\ 0.0737 \\ 0.0627 \end{array} \right]$$

and

$$\Sigma = 0.1, \left[\begin{array}{ccc} 0.2778 & 0.0387 & 0.0021 \\ 0.0387 & 0.1112 & -0.0020 \\ 0.0021 & -0.0020 & 0.0115 \end{array} \right].$$

This implies

$$G^T = \sqrt{0.1} \left[\begin{array}{ccc} 0.5271 & 0.0734 & 0.0040 \\ 0 & 0.3253 & -0.0070 \\ 0 & 0 & 0.1069 \end{array} \right]$$

We will make use of a simple helper functions to compute the inner product of two vectors and their sum.

```
public static double sum(double[] x)
{
  double r = 0.0;
  for (int i = 0; i < x.Length; ++i) r += x[i];
  return r;
}

public static double dot(double[] x, double[] y)
{
  double r = 0.0;
  for (int i = 0; i < x.Length; ++i) r += x[i] * y[i];
  return r;
}</pre>
```

Listing 7.1 demonstrates how the basic Markowitz model (7.3) is implemented using Fusion.

Listing 7.1: Code implementing problem (7.3).

```
/*
Purpose:
    Computes the optimal portfolio for a given risk

Input:
    n: Number of assets
    mu: An n dimmensional vector of expected returns
    GT: A matrix with n columns so (GT")*GT = covariance matrix"
    x0: Initial holdings
    w: Initial cash holding
    gamma: Maximum risk (=std. dev) accepted
```

```
Output:
    Optimal expected return and the optimal portfolio
public static double BasicMarkowitz
  (int n,
   double[] mu,
   double[,]GT,
   double[] x0,
   double w,
   double
            gamma)
 using( Model M = new Model("Basic Markowitz"))
    // Redirect log output from the solver to stdout for debugging.
    // ifuncommented.
    //M.SetLogHandler(Console.Out);
    // Defines the variables (holdings). Shortselling is not allowed.
    Variable x = M.Variable("x", n, Domain.GreaterThan(0.0));
    // Maximize expected return
   M.Objective("obj", ObjectiveSense.Maximize, Expr.Dot(mu,x));
    // The amount invested must be identical to intial wealth
   M.Constraint("budget", Expr.Sum(x), Domain.EqualsTo(w+sum(x0)));
    // Imposes a bound on the risk
   {\tt M.Constraint("risk", Expr.Vstack(gamma, Expr.Mul(GT, x)), Domain.InQCone());}\\
    // Solves the model.
   M.Solve();
   return dot(mu,x.Level());
 }
}
```

The source code should be self-explanatory except perhaps for

```
// Imposes a bound on the risk
M.Constraint("risk", Expr.Vstack(gamma,Expr.Mul(GT,x)), Domain.InQCone());
```

where the linear expression

$$\left[\begin{array}{c} \gamma G^T x \end{array}\right]$$

is created using the Expr.vstack operator. Finally, the linear expression must lie in a quadratic cone implying

$$\gamma \ge \left\| G^T x \right\|.$$

7.1.2 The Efficient Frontier

The portfolio computed by the Markowitz model is efficient in the sense that there no other other portfolio giving a strictly higher return for the same amount of risk. An efficient portfolio is also sometimes called a Pareto optimal portfolio. Clearly, an investor should only invest in efficient portfolios and therefore it may be relevant to present the investor for all efficient portfolios so the investor can choose the portfolio that has the desired tradeoff between return and risk.

Given a nonnegative α then the problem

maximize
$$\mu^T x - \alpha s$$

subject to $e^T x = w + e^T x^0$,
 $[s; G^T x] \in Q^{n+1}$,
 $x \geq 0$. (7.4)

computes an efficient portfolio. Note that the objective maximize the expected return while maximizing $-\alpha$ times the standard deviation. Hence, the standard deviation is minimized while α specifies the tradeoff between expected return and risk. Ideally the problem (7.4) should be solved for all values $\alpha \geq 0$ but in practice impossible. Using the example data from Section 7.1.1, the optimal values of return and risk for several α s are listed below:

```
Efficient frontier
alpha
                            risk

```

Example code

Listing 7.2 demonstrates how to compute the efficient portfolios for several values of α in Fusion.

Listing 7.2: Code for the computation of the efficient frontier based on problem (7.4).

```
Purpose:
      Computes several portfolios on the optimal portfolios by
          for alpha in alphas:
              maximize expected return - alpha * standard deviation
              subject to the constraints
  Input:
      n: Number of assets
      mu: An n dimmensional vector of expected returns
      GT: A matrix with n columns so (GT'')*GT = covariance\ matrix''
      x0: Initial holdings
      w: Initial cash holding
      alphas: List of the alphas
  Output:
      The efficient frontier as list of tuples (alpha, expected return, risk)
public static void EfficientFrontier
  (int n,
    double[]
                mu,
    double [,]
```

```
double[]
                x0,
    double
                w,
    double[]
                alphas,
    double[]
                frontier_mux,
    double[]
                frontier_s)
 using(Model M = new Model("Efficient frontier"))
    //M. SetLogHandler(Console. Out):
    // Defines the variables (holdings). Shortselling is not allowed.
    Variable x = M. Variable("x", n, Domain.GreaterThan(0.0)); // Portfolio variables
    Variable s = M.Variable("s", 1, Domain.Unbounded()); // Risk variable
   M.Constraint("budget", Expr.Sum(x), Domain.EqualsTo(w+sum(x0)));
    // Computes the risk
   M.Constraint("risk", Expr.Vstack(s,Expr.Mul(GT,x)),Domain.InQCone());
   Expression mudotx = Expr.Dot(mu,x);
    for (int i = 0; i < alphas.Length; ++i)</pre>
      // Define objective as a weighted combination of return and risk
      M.Objective("obj", ObjectiveSense.Maximize, Expr.Sub(mudotx,Expr.Mul(alphas[i],s)));
      M.Solve();
      frontier_mux[i] = dot(mu,x.Level());
      frontier_s[i]
                     = s.Level()[0];
 }
}
```

Note the efficient frontier could also have been computed using the code in Section 7.1.1 by varying γ . However, when the constraints of a *Fusion* model is changed the model has to be rebuild whereas a rebuild is not needed if only the objective is modified.

7.1.3 Improving the Computational Efficiency

In practice it is often important to solve the portfolio problem in a short amount of time. Therefore, in this section it is discussed what can be done at the modelling stage to improve the computational efficiency.

The computational cost is of course to some extent dependent on the number of constraints and variables in the optimization problem. However, in practice a more important factor is the number nonzeros used to represent the problem. Indeed it is often better to focus at the number of nonzeros in G see (7.2) and try to reduce that number by for instance changing the choice of G.

In other words if the computational efficiency should be improved then it is always good idea to start with focusing at the covariance matrix. As an example assume that

$$\Sigma = D + VV^T$$

where D is a positive definite diagonal matrix. Moreover, V is a matrix with n rows and p columns. Such a model for the covariance matrix is called a factor model index{factor model} and usually p is much smaller than n. In practice p tends be a small number independent of n say less than 100.

One possible choice for G is the Cholesky factorization of Σ which requires storage proportional to n(n+1)/2. However, another choice is

$$G^T = \left[D^{1/2}V^T \right]$$

because then

$$GG^T = D + VV^T$$
.

This choice requires storage proportional to n + pn which is much less than for the Cholesky choice of G. Indeed assuming p is a constant then the difference in storage requirements is a factor of n.

The example above exploits the so-called factor structure and demonstrates that an alternative choice of G may lead to a significant reduction in the amount of storage used to represent the problem. This will in most cases also lead to a significant reduction in the solution time.

The lesson to be learned is that it is important to investigate how the covariance is formed. Given this knowledge it might be possible to make a special choice for G that helps reducing the storage requirements and enhance the computational efficiency.

7.1.4 Slippage Cost

The basic Markowitz model assumes that there are no costs associated with trading the assets and that the returns of the assets is independent of the amount traded. None of those assumptions are usually valid in practice. Therefore, a more realistic model is

maximize
$$\mu^T x$$

subject to $e^T x + \sum_{j=1}^n T_j (x_j - x_j^0) = w + e^T x^0,$
 $x^T \Sigma x \leq \gamma^2,$
 $x \geq 0,$

$$(7.5)$$

where the function

$$T_j(x_j-x_i^0)$$

specifies the transaction costs when the holding of asset j is changed from its initial value.

7.1.5 Market Impact Costs

If the initial wealth is fairly small and no short selling is allowed, then the holdings will be small and then the amount traded of each asset must also be small. Therefore, it is reasonable to assume that the prices of the assets is independent of the amount traded. However, if a large volume of an assert is sold or purchased it can be expected that the price change and hence the expected return also change. This effect is called market impact costs. It is common to assume that the market impact cost for asset j can be modelled by

$$m_j \sqrt{|x_j - x_j^0|}$$

according where m_j is a constant that is estimated in some way. See [GK00] [p. 452] for details. Hence, we have

$$T_j(x_j - x_j^0) = m_j |x_j - x_j^0| \sqrt{|x_j - x_j^0|} = m_j |x_j - x_j^0|^{3/2}.$$

From [MOSEKApS12] it is known

$$\{(t,z): t \ge z^{3/2}, z \ge 0\} = \{(t,z): (s,t,z), (z,1/8,s) \in Q_r^3\}$$

where Q_r^3 is the 3 dimensional rotated quadratic cone. Hence, it follows

$$z_j = |x_j - x_j^0|, (s_j, t_j, z_j), (z_j, 1/8, s_j) \in Q_r^3, \sum_{j=1}^n T(x_j - x_j^0) = \sum_{j=1}^n t_j.$$

Unfortunately this set of constraints is nonconvex due to the constraint

$$z_j = |x_j - x_j^0| (7.6)$$

but in many cases the constraint may be replaced by the relaxed constraint

$$z_j \ge |x_j - x_j^0|. (7.7)$$

which is equivalent to

$$\begin{aligned}
 z_j &\geq x_j - x_j^0, \\
 z_j &\geq -(x_j - x_j^0).
 \end{aligned}
 \tag{7.8}$$

For instance if the universe of assets contains a risk free asset then

$$z_j > |x_j - x_j^0| (7.9)$$

cannot hold for an optimal solution.

Now given that the optimal solution has the property that (7.9) holds then the market impact costs within the model is larger than the true market impact cost and hence money are essentially considered garbage and removed by generating transaction costs. This may happen if a portfolio with very small risk is requested because then the only way to obtain a small risk is to get rid of some of the assets by generating transaction costs. It is assumed this is not the case and hence the models (7.6) and (7.7) are equivalent.

The above observations leads to

maximize
$$\mu^{T}x$$

subject to $e^{T}x + m^{T}t = w + e^{T}x^{0},$
 $(\gamma, G^{T}x) \in Q^{n+1},$
 $z_{j} \geq x_{j} - x_{j}^{0}, \quad j = 1, \dots, n,$
 $z_{j} \geq x_{j}^{0} - x_{j}, \quad j = 1, \dots, n,$
 $[v_{j}; t_{j}; z_{j}], [z_{j}; 1/8; v_{j}] \in Q_{r}^{3}, \quad j = 1, \dots, n,$
 $x \geq 0.$ (7.10)

The revised budget constraint

$$e^T x = w + e^T x^0 - m^T t$$

specifies that the total investment must be equal to the initial wealth minus the transaction costs. Moreover, observe the variables v and z are some auxiliary variables that model the market impact cost. Indeed it holds

$$z_j \ge |x_j - x_j^0|$$

and

$$t_j \ge z_i^{3/2}.$$

Tag proceeding it should be mentioned that transaction costs of the form

$$c_j \ge z_j^{p/q}$$

where p and q are both integers and $p \ge q$ can be modelled using quadratic cones. See [MOSEKApS12] for details.

Example code

Listing 7.3 demonstrates how to compute an optimal portfolio when market impact cost are included using Fusion.

Listing 7.3: Implementation of model (7.10).

```
Description:
        Extends the basic Markowitz model with a market cost term.
        n: Number of assets
        mu: An n dimmensional vector of expected returns
        GT: A matrix with n columns so (GT')*GT = covariance\ matrix'
        x0: Initial holdings
        w: Initial cash holding
        gamma: Maximum risk (=std. dev) accepted
        m: It is assumed that market impact cost for the j'th asset is
           m_{j}/x_{j}-x0_{j}/^{3}/2
    Output:
       Optimal expected return and the optimal portfolio
public static void MarkowitzWithMarketImpact
  (int n,
   double[] mu,
   double[,]GT,
   double[] x0,
   double w,
   double
            gamma.
   double[] m,
   double[] xsol,
   double[] tsol)
 using(Model M = new Model("Markowitz portfolio with market impact"))
    //M.SetLogHandler(Console.Out);
    // Defines the variables. No shortselling is allowed.
   Variable x = M.Variable("x", n, Domain.GreaterThan(0.0));
    // Addtional "helper" variables
   Variable t = M.Variable("t", n, Domain.Unbounded());
   Variable z = M.Variable("z", n, Domain.Unbounded());
   Variable v = M.Variable("v", n, Domain.Unbounded());
    // Maximize expected return
   M.Objective("obj", ObjectiveSense.Maximize, Expr.Dot(mu,x));
    // Invested amount + slippage cost = initial wealth
   M.Constraint("budget", Expr.Add(Expr.Sum(x),Expr.Dot(m,t)), Domain.EqualsTo(w+sum(x0)));
    // Imposes a bound on the risk
   M.Constraint("risk", Expr.Vstack(gamma,Expr.Mul(GT,x)), Domain.InQCone());
    // z >= |x-x0|
   M.Constraint("buy", Expr.Sub(z,Expr.Sub(x,x0)),Domain.GreaterThan(0.0));
   M.Constraint("sell", Expr.Sub(z,Expr.Sub(x0,x)),Domain.GreaterThan(0.0));
    // t \ge z^1.5, z \ge 0.0. Needs two rotated quadratic cones to model this term
   M.Constraint("ta", Expr.Hstack(v,t,z),Domain.InRotatedQCone());
   M.Constraint("tb", Expr.Hstack(z,Expr.ConstTerm(n,1.0/8.0),v),
                 Domain.InRotatedQCone());
```

```
M.Solve();

if (xsol != null)
   Array.Copy(x.Level(),xsol,n);
if (tsol != null)
   Array.Copy(t.Level(),tsol,n);
}
```

The major new feature compared to the previous examples are

```
// t \ge z^1.5, z \ge 0.0. Needs two rotated quadratic cones to model this term M.Constraint("ta", Expr.Hstack(v,t,z),Domain.InRotatedQCone());
```

and

In the first line the variables v, t and z are stacked horizontally which corresponds to creating a list of linear expressions where the j'th element has the form

$$\left[\begin{array}{c} v_j \\ t_j \\ z_j \end{array}\right]$$

and finally each linear expression are constrained to be in rotated quadratic cone i.e.

$$2v_jt_j \ge z_j^2$$
 and $v_j, t_j \ge 0$.

Similarly the second line is equivalent to the constraint

$$\left[\begin{array}{c} z_j \\ 1/8 \\ v_j \end{array}\right] \in Q_r^3$$

or equivalently

$$2z_j \frac{1}{8} \ge v_j^2$$
 and $z_j \ge 0$.

7.1.6 Transaction Costs

Now assume there is a cost associated with trading asset j and the cost is given by

$$T_{j}(\Delta x_{j}) = \left\{ \begin{array}{ll} 0, & \Delta x_{j} = 0, \\ f_{j} + g_{j} |\Delta x_{j}|, & \text{otherwise}. \end{array} \right.$$

 $Delta\ x_j$ is the change in the holding of asset j i.e.

$$\Delta x_j = x_j - x_j^0.$$

Hence, whenever asset j is traded a fixed cost of f_j has to be paid and a variable cost of g_j per unit traded. Given the assumptions about transaction costs in this section then problem (7.5) may be formulated as

maximize
$$\mu^{T}x$$

subject to $e^{T}x + \sum_{j=1}^{n}(f_{j}y_{j} + g_{j}z_{j}) = w + e^{T}x^{0},$
 $[\gamma; G^{T}x]$ $\in Q^{n+1},$
 z_{j} $\geq x_{j} - x_{j}^{0}, \quad j = 1, \dots, n,$
 z_{j} $\leq x_{j}^{0} - x_{j}, \quad j = 1, \dots, n,$
 z_{j} $\leq U_{j}y_{j}, \quad j = 1, \dots, n,$
 y_{j} $\in \{0, 1\}, \quad j = 1, \dots, n,$
 x $\geq 0.$ (7.11)

First observe that

$$z_j \ge |x_j - x_j^0|$$

and hence z_j is bounded below by $|\Delta x_j|$. U_j is some a prior chosen upper bound on the amount of trading in asset j and therefore if $z_j > 0$ then $y_j = 1$ has to be the case. This implies that the transaction costs for the asset j is given by autonomous

$$f_j y_j + g_j z_j.$$

Example code

The following example code demonstrates how to compute an optimal portfolio when transaction costs are included.

Listing 7.4: Code solve problem (7.11).

```
Description:
       Extends the basic Markowitz model with a market cost term.
   Input:
       n: Number of assets
       mu: An n dimmensional vector of expected returns
       GT: A matrix with n columns so (GT'')*GT = covariance matrix''
       x0: Initial holdings
       w: Initial cash holding
       gamma: Maximum risk (=std. dev) accepted
       f: If asset j is traded then a fixed cost f_j must be paid
       g: If asset j is traded then a cost g_{-}j must be paid for each unit traded
   Output:
      Optimal expected return and the optimal portfolio
public static double[] MarkowitzWithTransactionsCost
 (int n,
   double[] mu,
   double[,]GT,
   double[] x0,
   double
   double gamma,
   double[] f,
   double[] g)
 // Upper bound on the traded amount
 double[] u = new double[n];
   double v = w+sum(x0);
   for (int i = 0; i < n; ++i) u[i] = v;
 using( Model M = new Model("Markowitz portfolio with transaction costs") )
   Console.WriteLine("\n------
   Console.WriteLine("Markowitz portfolio optimization with transaction cost\n");
   Console.WriteLine("-----
\n");
```

```
//M.SetLogHandler(Console.Out);
            // Defines the variables. No shortselling is allowed.
           Variable x = M.Variable("x", n, Domain.GreaterThan(0.0));
           // Addtional "helper" variables
           Variable z = M.Variable("z", n, Domain.Unbounded());
            // Binary varables
           Variable y = M.Variable("y", n, Domain.Binary());
           // Maximize expected return
           M.Objective("obj", ObjectiveSense.Maximize, Expr.Dot(mu,x));
            // Invest amount + transactions costs = initial wealth
           M.Constraint("budget", Expr.Add(Expr.Add(Expr.Sum(x),Expr.Dot(f,y)),Expr.Dot(g,z)),
                                                Domain.EqualsTo(w+sum(x0)));
            // Imposes a bound on the risk
           M.Constraint("risk", Expr.Vstack(gamma,Expr.Mul(GT,x)), Domain.InQCone());
           M.Constraint("buy", Expr.Sub(z,Expr.Sub(x,x0)),Domain.GreaterThan(0.0));
           M.Constraint("sell", Expr.Sub(z,Expr.Sub(x0,x)),Domain.GreaterThan(0.0));
           //M.constraint("trade", Expr.hstack(z, Expr.sub(x,x0)), Domain.inqcone())"
           // Constraints for turning y off and on. z-diag(u)*y<=0 i.e. z_j \le u_j \le u_j
           M.Constraint("y_on_off", Expr.Sub(z,Expr.Mul(Matrix.Diag(u),y)), Domain.LessThan(0.0));
           // Integer optimization problems can be very hard to solve so limiting the
           // maximum amount of time is a valuable safe guard
           M.SetSolverParam("mioMaxTime", 180.0);
           M.Solve():
           Console.WriteLine("Expected return: {0:e4} Std. deviation: {1:e4} Transactions cost: {2:e4}
                               dot(mu, x.Level()), gamma, dot(f, y.Level()) + dot(g, z.Level()));
           return x.Level();
      }
}
```

7.2 Primal Support-Vector Machine (SVM)

Machine-Learning (ML) has become a common widespread tool in many applications that affect our everyday life. In many cases, at the very core of these techniques there is an optimization problem. This case studies focuses on the Support-Vector Machine (SVM).

In words, the basic SVM model can be stated as:

We are given a set of points m in a n-dimensional space, partitioned in two groups. Find, if any, the separating hyperplane of the two subsets with the largest margin, i.e. as far as possible from the points.

Mathematical Model

We must determine an hypeplane $w^T x = b$ that separate two sets of points leaving the largest margin possible. It can be proved that the margin is given by 2||w|| (see |CV95|).

Therefore, we need to solve the problem of maximizing 2||w|| with respect of w, b with the constraints that points of the same class must lie on the same side of the hyperplane. Denoting with $x_i \in \mathbb{R}^n$ the i-th observation and assuming that each point is given a label $y_i \in \{-1, +1\}$, it is easy to see that the separation is equivalent to:

$$y_i(w^T x_i - b) > 1.$$

The separating hyperplane is the solution of the following optimization problem:

$$\begin{aligned} & \text{minimize}_{b,w} & & \frac{1}{2} \|w\|^2 \\ & & y_i(w^T x_i - b) \geq 1 \quad i = 1, \dots, m \end{aligned}$$

If a solution exists, w, b define the separating hyperplane and the sign of $w^T x - b$ can be used to decide the class in which a point x falls.

To allow more flexibility the soft-margin SVM classifier is often used instead. It allows for violation of the classification. To this extent a non-negative slack variable is added to each linear constraint and penalized in the objective function.

minimize_{b,w}
$$\frac{1}{2} ||w||^2 + C \sum_{i=1}^m \xi_i$$

$$y_i(w^T x_i - b) \ge 1 - \xi_i \quad i = 1, \dots, m$$

$$\xi_i \ge 0 \qquad \qquad i = 1, \dots, m$$

In matrix form we have

$$\begin{aligned} & \text{minimize}_{b,w,\xi} & & \frac{1}{2}\|w\|^2 + C\mathbf{e}^T\xi \\ & & y\star(Xw-b\mathbf{e}) + \xi \geq \mathbf{e} \\ & & \xi \geq 0 \end{aligned}$$

where \star denotes the component-wise product, and **e** a vector with all components equal to one. The constant $C \geq 0$ acts both as scaling factor and as weight. Varying C yields different trade-off between accuracy and robustness.

Implementing the matrix formulation of the soft-margin SVM in *Fusion* is very easy. We only need to cast the problem in conic form, which in this case only involves converting the quadratic term of the objective function in a conic constraint:

minimize_{b,w,\xi,t}
$$t + C\mathbf{e}^T \xi$$

 $\xi + y \star (Xw - b\mathbf{e}) \ge \mathbf{e}$
 $(1,t,w) \in \mathcal{Q}_r^{n+2}$
 $\xi > 0$ (7.12)

where \mathcal{Q}_{∇} denotes a rotated cone of dimension n+2.

Fusion implementation

We show now how implement model (7.12). Let assume now we are given an array y of labels, a matrix X where input data are stored row-wise and a set of values CC for we want to test. The implementation in *Fusion* of our conic model starts declaring the model class:

```
Model M = new Model("Primal SVM");
```

Then we proceed defining the variables

```
Variable w = M.Variable( n, Domain.Unbounded());
Variable t = M.Variable( 1, Domain.Unbounded());
Variable b = M.Variable( 1, Domain.Unbounded());
Variable xi = M.Variable( m, Domain.GreaterThan(0.0));
```

The conic constraint is obtained stacking the three values

```
M.Constraint( Expr.Vstack( 1.0, t, w) , Domain.InRotatedQCone());
```

Note how the dimension of the cone is deduced from the arguments. The relaxed classification constranints can be expressed using the built-in expressions available in *Fusion*. In particular, it is very helpful to

- 1. use the element wise multiplication to perform $y \star \cdot$, using the Expr. mulElm function;
- 2. construct a vector whose entries are all repetition of b by calling Var. repeat.

The results is

Finally, the objective function is defined as

```
M.Objective(ObjectiveSense.Minimize, Expr.Add( t, Expr.Mul(c, Expr.Sum(xi) ) );
```

Since our aim is to solve sequence of problem varying C, then we can simply iterates along those values changing the objective function:

```
Console.WriteLine(" c | b | w");
for(int i=0; i<nc; i++)
{
   double c= 500.0*i;
   M.Objective(ObjectiveSense.Minimize, Expr.Add( t, Expr.Mul(c, Expr.Sum(xi) ) ));
   M.Solve();

Console.WriteLine("{0} | {1} |", c,b.Level()[0] );
   for(int j=0; j<n;j++)
        Console.Write(" {0}", w.Level()[j] );
   Console.WriteLine("\n");
}</pre>
```

The overall code follows:

Listing 7.5: The code implementing model (7.12)

```
Model M = new Model("Primal SVM");
try
{
  Console.WriteLine("Number of data
                                       : \{0\} \n'',m);
  Console.WriteLine("Number of features: {0}\n",n);
  Variable w = M.Variable( n, Domain.Unbounded());
 Variable t = M.Variable( 1, Domain.Unbounded());
 Variable b = M.Variable( 1, Domain.Unbounded());
 Variable xi = M.Variable( m, Domain.GreaterThan(0.0));
 M.Constraint( Expr.Add(Expr.MulElm( y, Expr.Sub( Expr.Mul(X,w), Var.Repeat(b,m) ) ), xi ),
                Domain.GreaterThan( 1.0 ) );
 M.Constraint( Expr.Vstack( 1.0, t, w) , Domain.InRotatedQCone());
 M.AcceptedSolutionStatus(AccSolutionStatus.NearOptimal);
  Console.WriteLine(" c | b
                                     | w");
  for(int i=0; i<nc; i++)</pre>
  {
   double c= 500.0*i;
   M.Objective(ObjectiveSense.Minimize, Expr.Add( t, Expr.Mul(c, Expr.Sum(xi) ) );
   M.Solve();
   Console.WriteLine("{0} | {1} |", c,b.Level()[0] );
```

Computational Tests

We show now few simple tests.

We generate random data composed by two sets of points using the following code:

```
int nc = 10;
int m = 50;
int n = 3;
int seed = 1;
double variance = 1.0;
double mean = 1.0;
Random gen = new Random(seed);
int nump= gen.Next(m);
double [] y= new double[m];
for(int i=0; i < nump; i++) y[i] = 1.0;</pre>
for(int i=nump; i < m; i++) y[i]= -1.0;</pre>
double [,] X = new double[m,n];
for(int i=0; i<nump; i++)</pre>
   for (int j = 0; j < n; j++)
      double xx = Math.Sqrt( -2.0*Math.Log(gen.NextDouble()) );
      double yy = Math.Sin(2.0*Math.PI*gen.NextDouble());
      X[i, j] = (xx*yy) * variance + mean;
```

As first tests, we generate two sets of random two dimensional points each from a Gaussian distribution: we use a set centered at (1.0, 1.0) and another at (-1.0, -1.0).

With a standard deviation $\sigma = 1/2$ we obtain a separable sets of points and for C we obtain the result in Fig. 7.1.

For $\sigma = 1$ separability is lost and we obtain the hyper plane as for Fig. 7.2.

7.3 2D Total Variation

This case studies is mainly based on the paper by Goldfarb and Yin [GY05].

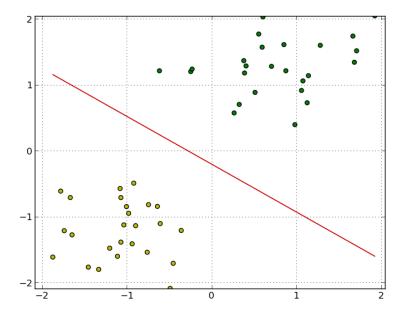

Fig. 7.1: Separating hyper plane for two group of points in two dimensions.

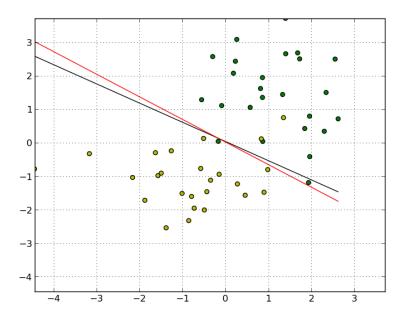

Fig. 7.2: Soft separating hyper plane for two group of points in two dimensions.

Mathematical Formulation

We are given a $n \times m$ grid and for each cell (i, j) an observed value f_{ij} that can expressed as

$$f_{ij} = u_{ij} + v_{ij},$$

where u_{ij} is the actual value and v_{ij} is the noise. The aim is to reconstruct f subtracting the noise from the observations.

We assume the 2-norm of the overall noise to be bounded: the corresponding constraint is

$$||u - f||_2 \le \sigma$$

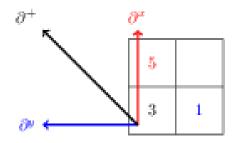

which translate in a simple conic quadratic constraint as

$$(\sigma, u - f) \in \mathcal{Q}$$

Then our aim is to minimized the change in both axis moving from one cell to the adjacent ones. To this end we define the adjacent differences vector as

$$\partial_{ij}^{+} = \begin{pmatrix} \partial_{ij}^{x} \\ \partial_{ij}^{y} \end{pmatrix} = \begin{pmatrix} u_{i+1,j} - u_{i,j} \\ u_{i,j+1} - u_{i,j} \end{pmatrix}, \tag{7.13}$$

for each pair of cells $1 \leq i, j \leq n$. The idea is depicted in the following figure.

For each cells we want to minimize the norm of ∂_{ij}^+ , and therefore we introduce auxiliary variables t_{ij} such that

$$t_{ij} \ge \|\partial_{ij}^+\|_2 \quad \forall i, j,$$

that we reformulate as

$$(t_{ij}, \partial_{ij}^+) \in \mathcal{Q} \quad \forall i, j,$$

and minimize the sum of all t_{ij} .

The complete model takes the form:

min
$$\sum_{1 \leq i,j \leq n} t_{ij}$$

$$\partial_{ij}^{+} = (u_{i+1,j} - u_{i,j}, u_{i,j+1} - u_{i,j})^{T} \quad \forall 1 \leq i, j \leq n$$

$$(t_{ij}, \partial_{ij}^{+}) \in \mathcal{Q} \qquad \forall 1 \leq i, j \leq n$$

$$(\sigma, \text{vect}(u - f)) \in \mathcal{Q}$$

$$u_{i,j} \in [0, 1] \qquad \forall 1 \leq i, j \leq n$$

$$(7.14)$$

63

7.3. 2D Total Variation

Implementation

The Fusion implementation of model (7.14) relies on the possibility of define variable and expression slices.

First of all we start creating the optimization model and variables t and u:

Note how u is larger than the actual grid dimension to account for additional cells. Then we define a slice of u that contains the actual cells of the grid:

```
Variable ucore = u.Slice(new int[] { 0, 0 }, new int[] { nrows, ncols });
```

The next steps is to define the partial variation on each axis, as in (7.13):

Slices are in this case created on the fly as they are not going to be reused thereafter. Now we can set the conic constraints on the norm of the total variations. To this extent:

- 1. we proceed flattening deltax, deltay and t so that they become three one-dimensional arrays;
- 2. they can then be stacked horizontally using Expr. hstack, obtaining a matrix of expressions
- 3. each row of that matrix can be assigned to a rotated quadratic cone simply using Domain.inRotatedQCone.

All these steps can be condensed in the following line:

```
M.Constraint(Expr.Stack(2, t, deltax, deltay), Domain.InQCone().Axis(2));
```

We need now to bound the norm of the error cell-wise. A conic constraint suffices using f as an one-dimensional array:

We only need to set the objective function as the sum of all t_{ij} 's:

```
M.Objective(ObjectiveSense.Minimize, Expr.Sum(t));
```

The overall code follows.

Listing 7.6: The Fusion implementation of model (7.14).

```
using System;
using mosek.fusion;

namespace mosek
{
   namespace fusion
```

```
namespace example
           public class total_variation
               public static void Main(string[] args)
                   int ncols = 50:
                   int nrows = 50;
                   int seed = 0;
                   double sigma = 1.0;
                   int ncells = nrows * ncols;
                   Random gen = new Random(seed);
                   double[] f = new double[ncells];
                   for (int i = 0; i < ncells; i++)</pre>
                     double xx = Math.Sqrt(-2.0 * Math.Log(gen.NextDouble()));
                     double yy = Math.Sin(2.0 * Math.PI * gen.NextDouble());
                     f[i] = Math.Max(Math.Min(1.0, xx*yy), .0);
                   Model M = new Model("TV");
                   try
                   {
                     Variable u = M.Variable(new int[]{ nrows + 1, ncols + 1},
                                              Domain.InRange(0.0, 1.0));
                     Variable t = M.Variable(new int[]{nrows , ncols }, Domain.Unbounded());
                     Variable ucore = u.Slice(new int[] { 0, 0 }, new int[] { nrows, ncols });
                     Expression deltax = Expr.Sub(u.Slice(new int[] { 1, 0 },
                                                           new int[] { nrows + 1, ncols }),
                                                   ucore):
                     Expression deltay = Expr.Sub(u.Slice(new int[] { 0, 1 },
                                                           new int[] { nrows, ncols + 1 }),
                                                   ucore);
                     M.Constraint(Expr.Stack(2, t, deltax, deltay), Domain.InQCone().Axis(2));
                     Matrix mat_f = Matrix.Dense(nrows,ncols,f);
                     M.Constraint(Expr.Vstack( sigma, Expr.Flatten( Expr.Sub(ucore, mat_f)) ),
                                   Domain.InQCone());
                       boundary conditions are not actually needed
                       M.constraint(Expr.sub(u.slice([n-1,0],[n,m]), u.
\hookrightarrow slice([n,0],[n+1,m])),
                       Domain.equalsTo(0.));
                       M.constraint(Expr.sub(u.slice([0,n-1],[n,m]), u.
\hookrightarrowslice([0,n],[n,m+1])),
                       Domain.equalsTo(0.));
                     M.SetLogHandler(Console.Out);
                     M.Objective(ObjectiveSense.Minimize, Expr.Sum(t));
```

7.4 Inner and outer Löwner-John Ellipsoids

In this section we show how to compute the Löwner-John *inner* and *outer* ellipsoidal approximations of a polytope.

This is possible because for a given polytope, the volume of the inscribed (or enclosing) ellipsoid is proportional to a the n-th power of the determinant of the a specific positive semidefinite matrix. Details are given in Section 7.4.3.

7.4.1 Inner Löwner-John Ellipsoids

The inner ellipsoidal approximation to a polytope

$$S = \{ x \in \mathbb{R}^n \mid Ax \le b \}$$

maximizes the volume of the inscribed ellipsoid,

$${x \mid x = Cu + d, ||u||_2 \le 1}.$$

The volume is proportional to $\det(C)^{1/n}$, so the problem can be solved as

maximize
$$t$$
 subject to $t \leq \det(C)^{1/n}$
$$||Ca_i||_2 \leq b_i - a_i^T d, \ i = 1, \dots, m$$

$$C \succeq 0$$

$$(7.15)$$

which is equivalent to a mixed conic quadratic and semidefinite programming problem.

The source code follows in Listing 7.7. See also Section 7.4.3.

Listing 7.7: Fusion implementation of model (7.15).

```
public static double[][] lownerjohn_inner(double[][] A, double[] b)
{
    using( Model M = new Model("lownerjohn_inner"))
    {
        // Direct log output to the terminal for debugging.
        M.SetLogHandler(Console.Out);
        int m = A.Length;
        int n = A[0].Length;

        // Setup variables
        Variable t = M.Variable("t", 1, Domain.GreaterThan(0.0));
        Variable C = M.Variable("C", new int[]{n,n}, Domain.Unbounded());
        Variable d = M.Variable("d", n, Domain.Unbounded());
```

```
// (bi - ai^T*d, C*ai) \in Q
   for (int i = 0; i < m; ++i)
     M.Constraint( "qc" + i, Expr.Vstack(Expr.Sub(b[i],Expr.Dot(A[i],d)), Expr.Mul(C,A[i])),
                    Domain.InQCone() );
    // t <= det(C)^{1/n}
   det_rootn(M, C, t);
    // Objective: Maximize t
   M.Objective(ObjectiveSense.Maximize, t);
   M.Solve();
   double[] Clvl = C.Level();
   double[] dlvl = d.Level();
   double[][] Cres_d = new double[n+1][];
   for (int i = 0; i < n; ++i)
      Cres_d[i] = new double[n];
      System.Array.Copy(Clvl,i*n,Cres_d[i],0, n);
    Cres_d[n] = dlvl;
    return Cres_d;
 }
}
```

7.4.2 Outer Löwner-John Ellipsoids

The outer ellipsoidal approximation to a polytope given as the convex hull of a set of points

$$S = \text{conv}\{x_1, x_2, \dots, x_m\}$$

minimizes the volume of the enclosing ellipsoid,

$${x \mid ||P(x-c)||_2 < 1}$$

The volume is proportional to $det(P)^{-1/n}$, so the problem can be solved as

minimize
$$t$$

subject to $t \ge \det(P)^{-1/n}$
 $\|Px_i + c\|_2 \le 1, i = 1, \dots, m$
 $P \succ 0.$ (7.16)

The source code follows in Listing 7.8. See also Section 7.4.3.

Listing 7.8: Fusion implementation of model (7.16).

```
public static double[][] lownerjohn_outer(double[][] x)
{
    using( Model M = new Model("lownerjohn_outer") )
    {
        // Direct log output to the terminal for debugging.
        M.SetLogHandler(Console.Out);
        int m = x.Length;
        int n = x[0].Length;

        // Setup variables
        Variable t = M.Variable("t", 1, Domain.GreaterThan(0.0));
        Variable P = M.Variable("P", new int[]{n,n}, Domain.Unbounded());
        Variable c = M.Variable("c", n, Domain.Unbounded());
```

```
// (1, P(*xi+c)) \in Q
   for (int i = 0; i < m; ++i)
     M.Constraint( "qc" + i, Expr.Vstack(Expr.Ones(1), Expr.Sub(Expr.Mul(P,x[i]), c)),
                    Domain.InQCone() );
    // t \le det(P)^{1/n}
   det_rootn(M, P, t);
    // Objective: Maximize t
   M.Objective(ObjectiveSense.Maximize, t);
   M.Solve();
   double[] Plvl = P.Level();
   double[] clvl = c.Level();
   double[][] Pc = new double[n+1][];
   for (int i = 0; i < n; ++i)
      Pc[i] = new double[n];
      System.Array.Copy(Plvl,i*n, Pc[i],0, n);
   Pc[n] = clv1;
    return Pc;
 }
}
```

7.4.3 Bound on the Determinant Root.

Using SDP variables it is possible to bound the n-power of the determinant of a positive definite matrix, by modeling its hypograph:

$$C = \{ (X, t) \in \mathcal{S}_{+}^{n} \times \mathbb{R} | t \le \det(X)^{1/n} \}$$
 (7.17)

The set (7.17) can be modeled as the intersection of a semidefinite cone

$$[X, Z; Z^T Diag(Z)] > 0$$

and a number of rotated quadratic cones and affine hyperplanes,

$$t \le (Z11 * Z22 * ... * Znn)^{1/n},$$

which model the geometric mean hypograph

$$S = \{(x,t) \in \mathbb{R}^n \times \mathbb{R} | x \ge 0, t \le \prod_i x_i (x_1 \cdot x_2 \cdot \dots \cdot x_n)^{(1/n)} \}$$

as the intersection of rotated quadratic cones and affine hyperplane.

See [BenTalN01] for further reading.

The Fusion implementation of the constraint on the n-th power of the root of the determinant is reported in Listing 7.9.

Listing 7.9: Bound on the root determinant n-th power, see (7.17).

```
public static void det_rootn(Model M, Variable X, Variable t)
{
  int n = X.GetShape().Dim(0);

// Setup variables
```

```
Variable Y = M.Variable(Domain.InPSDCone(2*n));

// Setup Y = [X, Z; Z^T diag(Z)]
Variable Y11 = Y.Slice(new int[] {0, 0}, new int[] {n, n});
Variable Y21 = Y.Slice(new int[] {n, 0}, new int[] {2*n, n});
Variable Y22 = Y.Slice(new int[] {n, n}, new int[] {2*n, 2*n});

M.Constraint( Expr.Sub(Expr.MulElm(Matrix.Eye(n),Y21), Y22), Domain.EqualsTo(0.0));
M.Constraint( Expr.Sub(X, Y11), Domain.EqualsTo(0.0) );

// t^n <= (Z11*Z22*...*Znn)
Variable[] tmpv = new Variable[n];
for (int i = 0; i < n; ++i) tmpv[i] = Y22.Index(i,i);
Variable z = Var.Reshape(Var.Vstack(tmpv), n);
geometric_mean(M, z, t);
}</pre>
```

The code is relies on a recursive implementation of the constraint on the geometric mean, as in Listing 7 10

Listing 7.10: Bound on the geometric mean.

```
public static void geometric_mean(Model M, Variable x, Variable t)
 int n = (int)x.Size();
 int 1 = (int)System.Math.Ceiling(log2(n));
 int m = pow2(1) - n;
 Variable x0;
  if (m == 0)
     x0 = x;
  else
     x0 = Var.Vstack(x, M.Variable(m, Domain.GreaterThan(0.0)));
 Variable z = x0;
 for (int i = 0; i < 1-1; ++i)
    Variable xi = M.Variable(pow2(1-i-1), Domain.GreaterThan(0.0));
   for (int k = 0; k < pow2(1-i-1); ++k)
     M.Constraint(Var.Vstack(z.Index(2*k),z.Index(2*k+1),xi.Index(k)),
                   Domain.InRotatedQCone());
     z = xi;
 }
 Variable t0 = M.Variable(1, Domain.GreaterThan(0.0));
 M.Constraint(Var.Vstack(z, t0), Domain.InRotatedQCone());
 M.Constraint(Expr.Sub(Expr.Mul(System.Math.Pow(2,0.5*1),t),t0), Domain.EqualsTo(0.0));
 for (int i = pow2(1-m); i < pow2(1); ++i)
   M.Constraint(Expr.Sub(x0.Index(i), t), Domain.EqualsTo(0.0));
```

7.5 Nearest Correlation Matrix Problem

In the nearest correlation problem we are given a symmetric matrix A and we wish to find the closest correlation matrix, with respect to a given norm. A correlation matrix must be a positive-semidefinite matrix. In the next sections we will show two typical approaches:

- use the *Frobenius norm*,
- use the so-called *nuclear norm*.

In both cases we can exploit the symmetry of the correlation matrix to reduce the problem dimension. We will make use of the following mapping from a symmetric matrix to vector containing the (scaled) lower triangular part of the matrix,

$$\operatorname{vec}(M) : \mathbb{R}^{n \times n} \to \mathbb{R}^{n(n+1)/2}
\operatorname{vec}(M)_k = M_{ij} & \text{for } k = i(i+1)/2 + j, i = j
\operatorname{vec}(M)_k = \sqrt{2}M_{ij} & \text{for } k = i(i+1)/2, i < j.$$
(7.18)

In Listing 7.11 the Fusion implementation of vec.

Listing 7.11: Implementation of function vec in (7.18).

```
public static Expression Vec(Expression e)
  int N
           = e.GetShape().Dim(0);
  int[] msubi = new int[N*(N+1)/2],
       msubj = new int[N*(N+1)/2];
  double[] mcof = new double[N*(N+1)/2];
    for (int i = 0, k = 0; i < N; ++i)
      for (int j = 0; j < i+1; ++j, ++k)
        msubi[k] = k;
        msubj[k] = i*N+j;
        if (i == j) mcof[k] = 1.0;
                   mcof[k] = Math.Sqrt(2);
      }
 }
  var S = Matrix.Sparse(N * (N+1) / 2,N * N,msubi,msubj,mcof);
  return Expr.Mul(S,Expr.Flatten(e));
}
```

7.5.1 Nearest Correlation with Frobenius Norm

In this section we use the Frobineus norm, i.e. the nearest correlation matrix is given by

$$X^{\star} = \arg\min_{x \in S} \|A - X\|_F$$

where

$$S = \{X \in \mathbb{R}^{n \times n} \mid X \succeq 0, \mathbf{diag}(X) = e\}.$$

To exploit symmetry of A - X we use the *vec* mapping in (7.18). We then get an optimization problem with both conic quadratic and semidefinite constraints,

minimize
$$t$$
 subject to $(t, \text{vec}(A - X)) \in \mathcal{Q}$ $\mathbf{diag}(X) = e$ $X \succeq 0,$ (7.19)

Source code: Nearest correlation

The code implementing problem (7.19) is reported in Listing 7.12.

Listing 7.12: Implementation of problem (7.19).

```
public static void nearestcorr_frobenius(Matrix A)
    int N = A.NumRows();
  // Create a model with the name 'NearestCorrelation
 using (var M = new Model("NearestCorrelation"))
    // Setting up the variables
   var X = M.Variable("X", Domain.InPSDCone(N));
    var t = M.Variable("t", 1, Domain.Unbounded());
    // (t, vec (A-X)) \in Q
   M.Constraint( Expr.Vstack(t, Vec(Expr.Sub(A,X))), Domain.InQCone() );
    // diag(X) = e
   M.Constraint(X.Diag(), Domain.EqualsTo(1.0));
    // Objective: Minimize t
   M.Objective(ObjectiveSense.Minimize, t);
    // Solve the problem
   M.Solve();
    // Get the solution values
   Console.WriteLine("X = n\{0\}", mattostr(X.Level(), N));
    Console.WriteLine("t = {0}", mattostr(t.Level(), N));
 }
}
```

We use the following input

Listing 7.13: Input for the nearest correlation problem.

```
int N = 5;
var A = Matrix.Dense( new double[,]
    { 0.0, 0.5, - 0.1, -0.2, 0.5},
        { 0.5, 1.25, -0.05, -0.1, 0.25},
        {-0.1, -0.05, 0.51, 0.02, -0.05},
        {-0.2, -0.1, 0.02, 0.54, -0.1},
        { 0.5, 0.25, -0.05, -0.1, 1.25} });
```

The expected out is the following (small differences may apply):

```
X =
[ 1.000e+000 5.000e-001 -1.000e-001 -2.000e-001 5.000e-001]
[ 5.000e-001 1.000e+000 -5.000e-002 -9.999e-002 2.500e-001]
[ -1.000e-001 -5.000e-002 1.000e+000 2.000e-002 -5.000e-002]
[ -2.000e-001 -9.999e-002 2.000e-002 1.000e+000 -9.999e-002]
[ 5.000e-001 2.500e-001 -5.000e-002 -9.999e-002 1.000e+000]
```

7.5.2 Nearest Correlation with Nuclear-norm Penalty

This is a variation of the nearest correlation matrix, where we estimate a correlation matrix $X \geq 0$, where $X - \mathbf{diag}(w) \geq 0$ has low rank induced by a nuclear norm constraint, and $w \geq 0$.

We solve the problem

```
minimize \|X + \mathbf{diag}(w) - A\|_F + \gamma \text{Tr}(X)
subject to X \succeq 0, w \geq 0.
```

Again we can exploit symmetry of A - X using the *vec* mapping in (7.18). We then get an optimization problem with both conic quadratic and semidefinite constraints.

```
\begin{array}{ll} \text{minimize} & t + \gamma \text{Tr}(X) \\ \text{subject to} & (t, \text{vec}(X + \mathbf{diag}(w) - A)) & \in \mathcal{Q} \\ & X \in \mathcal{S}_+, w \geq 0 \end{array}
```

The source code for this example follows in Listing 7.14.

Listing 7.14: Nearest correlation with nuclear norm.

```
public static void nearestcorr_nn(Matrix A, double[] gammas, double[] res, int[] rank)
    int N = A.NumRows();
   using (var M = new Model("NucNorm"))
      // Setup variables
      var t = M.Variable("t", 1, Domain.Unbounded());
      var X = M.Variable("X", Domain.InPSDCone(N));
      var w = M.Variable("w", N, Domain.GreaterThan(0.0));
      // (t, vec (X + diag(w) - A)) in Q
      var D = Expr.MulElm( Matrix.Eye(N), Var.Repeat(w,1,N) );
      M.Constraint( Expr.Vstack( t, Vec(Expr.Sub(Expr.Add(X, D), A)) ), Domain.InQCone() );
      //M.SetLogHandler(Console.Out);
      var d = new double[N];
      for (var k = 0; k < gammas.Length; ++k)</pre>
        // Objective: Minimize t + gamma*Tr(X)
        var gamm_trX = Expr.Mul(gammas[k], Expr.Sum(X.Diag()) );
        M.Objective(ObjectiveSense.Minimize, Expr.Add(t, gamm_trX ) );
        M.Solve();
        var X1 = X.Level();
        var wl = w.Level();
        var r_sqr = 0.0;
        for (var j = 0; j < N; ++j)
          for (var i = j+1; i < N; ++i)
            r_sqr += 2*(A.Get(j,i) - Xl[i+j*N])*(A.Get(j,i) - Xl[i+j*N]);
        for (var i = 0; i < N; ++i)
          r_{sqr} += (A.Get(i,i) - Xl[i+i*N] - wl[i])*(A.Get(i,i) - Xl[i+i*N] - wl[i]);
        mosek.LinAlg.syeig(mosek.uplo.lo,N, X.Level(), d);
        var rnk = 0; foreach (var v in d) if (v > 1e-6) ++rnk;
        res[k] = Math.Sqrt(r_sqr);
        rank[k] = rnk;
      }
   }
}
```

We feed **MOSEK** with the same input as in Section 7.5.1. The problem is solved for a range of gamma values, to show how the penalty term helps achieve low rank solution. To this extent we report both the

rank of the solution and the norm residual. The rank is computed using the LinAlg.syeig available in the MOSEK.

```
gamma = 0.0, res=3.076e-01, rank = 4
gamma = 0.1, res=4.252e-01, rank = 2
gamma = 0.2, res=5.112e-01, rank = 1
gamma = 0.3, res=5.298e-01, rank = 1
gamma = 0.4, res=5.593e-01, rank = 1
gamma = 0.5, res=6.046e-01, rank = 1
gamma = 0.6, res=6.764e-01, rank = 1
gamma = 0.7, res=8.010e-01, rank = 1
gamma = 0.8, res=1.062e+00, rank = 1
gamma = 0.9, res=1.130e+00, rank = 0
gamma = 1.0, res=1.130e+00, rank = 0
```

7.6 Semidefinite Relaxation of MIQCQP Problems

In this case studies we will discuss a fairly common application for Semidefinite Optimization: to define continuous coninc relaxation of Mixed-Integer optimization problems.

We will focus on problems of the form:

$$\min \quad x^T P x + 2q^T x$$

$$x \in \mathbb{Z}^n$$
(7.20)

where $q \in \mathbb{R}^n$ and $P \in \mathcal{S}_+^{n \times n}$. There are many important problems that can be reformulated as problem (7.20):

- integer least squares problem $\min ||Ax b||_2^2$, s.t. $x \in \mathbb{Z}^n$
- closest vector problem min $||v z||_2$, s.t. $z \in \{Bx | x \in \mathbb{Z}^n\}$

Following [PB15], we can derive a continuous conic model. We first relax the integrality constraint

$$\min \quad x^T P x + 2q^T x$$

$$x_i(x_i - 1) \ge 0 \quad i = 1, \dots, n.$$

The last constraint is still non-convex. We introduce a new variable $X \in \mathbb{R}^{n \times n}$, such that $X = x \cdot x^T$. The last constraint then reads

$$\mathbf{diag}(X) - x \ge 0,$$

and with few passages we can write

min
$$\mathbf{Tr}(PX) + 2q^T x$$

 $\mathbf{diag}(X) \ge x$
 $X = x \cdot x^T$.

To get a conic problem we relax the last constraint and apply the Schur complement. The final relaxation follows:

min
$$\operatorname{Tr}(PX) + 2q^T x$$

$$\operatorname{diag}(X) \ge x$$

$$\begin{bmatrix} X & x \\ x^T & 1 \end{bmatrix} \in \mathcal{S}_+^n.$$
(7.21)

We refer to [PB15] for more details.

Fusion Implementation

Implementing model (7.21) in Fusion is very simple. We assume we are given as input n, P and q. Then we proceed creating the optimization model

```
using (Model M = new Model())
{
```

The important step is to define a single PSD variable

$$Z = \left[\begin{array}{cc} X & x \\ x^T & 1 \end{array} \right] \in \mathcal{S}_+^{n+1}.$$

Our code will create Z and two slices that corresponds to X, x:

```
Variable Z = M.Variable(n+1, Domain.InPSDCone());

Variable X= Z.Slice(new int[]{0,0},new int[]{n,n});
Variable x= Z.Slice(new int[]{0,n},new int[]{n,n+1});
```

The constraints are declared as follow

```
M.Constraint( Expr.Sub(X.Diag(),x), Domain.GreaterThan(0.0) );

M.Constraint( Z.Index(n,n), Domain.EqualsTo(1.0));
```

The objective function uses several available linear expressions:

```
Expression two_xq = Expr.Mul(2.0, Expr.Dot( x, q) );
Expression trPX = Expr.Sum(Expr.MulElm( Matrix.Dense(n,n,P), X ));
M.Objective( ObjectiveSense.Minimize, Expr.Add( trPX , two_xq ) );
```

Note that the *trace* operator is not directly available in *Fusion*, but its definition can be easily used instead.

The complete code follows in Listing 7.15.

Listing 7.15: Fusion implementation of model (7.21).

```
using (Model M = new Model())
{
   Variable Z = M.Variable(n+1, Domain.InPSDCone());

Variable X= Z.Slice(new int[]{0,0},new int[]{n,n});
   Variable x= Z.Slice(new int[]{0,n},new int[]{n,n+1});
   M.Constraint( Expr.Sub(X.Diag(),x), Domain.GreaterThan(0.0) );

M.Constraint( Z.Index(n,n), Domain.EqualsTo(1.0));
   Expression two_xq = Expr.Mul(2.0, Expr.Dot( x, q) );
   Expression trPX = Expr.Sum(Expr.MulElm( Matrix.Dense(n,n,P), X ));
   M.Objective( ObjectiveSense.Minimize, Expr.Add( trPX , two_xq ) );
   Console.Write("solution status= %s\n",M.GetPrimalSolutionStatus());

M.Solve();
```

Numerical Examples

We present now some simple numerical experiments. The input data are generate following again [PB15].

1. We generate a matrix $A \in \mathbb{R}^{m \times n}$, such that whose entries are normally distributed, i.e. $A_{ij} = \mathcal{N}(0,1)$

- 2. define $P = AA^T$
- 3. generate a vector x_s whose entries are random number uniformly distributed in [0,1].
- 4. define $q = -Px_s$

These linear algebra operations are conveniently performed using the BLAS and LAPACK routines available through the Optimizer API for .NET.

```
// problem dimensions
int n = 50;
int m = 2*n;
Random rnd = new Random();
// problem data
double []A = new double[m*n];
double []xs = new double[n];
for(int j=0;j<n;j++)</pre>
 for(int i=0;i<m;i++)</pre>
    double u1 = rnd.NextDouble(); //these are uniform(0,1) random doubles
    double u2 = rnd.NextDouble();
    A[i*n+j] = Math.Sqrt(-2.0 * Math.Log(u1)) * Math.Sin(2.0 * Math.PI * u2);
 xs[j]= rnd.NextDouble();
double [] P = new double[n*n];
double [] q = new double[n];
//P = A ^T A
LinAlg.syrk(
 mosek.uplo.lo,
 mosek.transpose.no,
 n,m,1.0, A, 0.0, P);
//must fill P upper triangular
for(int j=0;j<n;j++)</pre>
 for(int i=j+1;i<n;i++)</pre>
    P[j*n+i] = P[i*n+j];
// q = -P xs
LinAlg.gemv(
 mosek.transpose.no,
 n, n,
  -1.0,
 Ρ,
 xs,
  0.0,
  q);
```

7.7 SUDOKU

SUDOKU is a famous simple yet mind-blowing simple game. The objective is to fill a 9×9 grid with digits so that each column, each row, and each of the nine 3×3 sub-grids that compose the grid (also called *boxes*, *blocks*, *regions*, or *sub-squares*) contains all of the digits from 1 to 9. For more information see http://en.wikipedia.org/wiki/Sudoku. Here is a simple example:

7.7. SUDOKU 75

			4				
5	8			3			
1		2	8		9		
7	3	1			8	4	
4	1			9	2	7	
	4		6	5		8	
		4			1	6	
			9				

_								
3	8	2	5	4	7	6	9	2
4	5	8	9	1	3	7	2	6
7	1	5	2	8	6	9	3	4
6	7	3	1	5	2	8	4	9
9	2	6	8	7	4	5	1	3
8	4	1	6	3	9	2	7	5
1	9	4	7	6	5	3	8	2
5	3	9	4	2	8	1	6	7
2	6	7	3	9	1	4	5	8

The solution

In a more general setting we are given a grid of dimension $n \times n$, with $n = m^2, m \in \mathbb{N}$. Each cell (i, j) must be filled with an integer $y_{ij} \in [1, n]$. Along each row and each column there must be no repetitions. No repetitions are allowed also in each sub-grid with corners $\{(mt+1), (ml+1), (m(l+1)), (m(l+1))\}$, for $t, l = 0, \ldots, m-1$.

In general, each SUDOKU instance comes along with some values already determined. The purpose of that values is:

- reduce the complexity of the game removing symmetries and guiding the initial moves of the player;
- ensure that there will be a unique solution.

The latter point requires a careful selection of the given cells, that is beyond the scope of this post. We only provide the model with the set F randomly generated. We represent such set in as list of triplets (i, j, v).

Note that SUDOKU is a **feasibility** problem. A typical Integer Programming formulation is straightforward: let x_{ijk} be a binary variable that takes 1 if k is put in cell (i, j). Then we look for a feasible solution of the system of constraints:

SUDOKU has been also a nice problem to fiddle with for many researchers in the optimization and related community. Indeed, its simple structure and the easy way in which the results can be tested, makes it a perfect test problem.

SUDOKU is a typical assignment problem. Its constraints are commonly found in optimization problems about scheduling, resource allocations.

We will approach SUDOKU as a standard integer linear program, and we will show how easily and elegantly it can be implemented in *Fusion*.

Mathematical Formulation

In this section we formulate SUDOKU as a mixed-integer linear optimization problem. Let's introduce a binary variable x_{ijk} that takes 1 if the digit k is put in the cell (i, j), or 0 otherwise. We must ask that for each cell only one digit is selected, i.e.

$$\sum_{k=0}^{n-1} x_{ijk} = 1 \qquad i, j = 0, \dots, n-1$$
 (7.22)

Similar constraints can be used to force each digit to appears only once in each row or column

$$\sum_{\substack{i=0\\ j=0}}^{n-1} x_{ijk} = 1 \quad j, k = 0, \dots, n-1$$

$$\sum_{\substack{i=0\\ j=0}}^{n-1} x_{ijk} = 1 \quad i, k = 0, \dots, n-1$$
 (7.23)

To force a digit to appears only once in each sub-grid we can use the following

$$\sum_{i=0}^{m-1} \sum_{j=0}^{m-1} x_{(i+tm)(j+tl)k} = 1 \qquad k = 0, \dots, n-1 \text{ and } t, l = 0, \dots, m-1$$
(7.24)

For each given cell (i, j) in F we must set the corresponding value k, i.e.

$$x_{ijk} = 1$$
.

Summarizing, and considering that there is no objective function to minimize, the optimization model for the SUDOKU problem takes the form

$$\min 0$$
s.t.
$$\sum_{i=0}^{n-1} x_{ijk} = 1 \qquad j, k = 0, \dots, n-1$$

$$\sum_{j=0}^{n-1} x_{ijk} = 1 \qquad i, k = 0, \dots, n-1$$

$$\sum_{k=0}^{n-1} x_{ijk} = 1 \qquad i, j = 0, \dots, n-1$$

$$\sum_{i=0}^{m-1} \sum_{j=0}^{m-1} x_{(i+tm)(j+tl)k} = 1 \qquad k = 0, \dots, n-1 \text{ and }$$

$$t, l = 0, \dots, m-1$$

$$x_{ijk} = 1 \qquad \forall (i, j, k) \in F$$

Implementation with Fusion

The implementation in Fusion is straightforward. First, we represent the x variable using a three dimensional Fusion variable:

```
Variable x = M.Variable(new int[] { n, n, n }, Domain.Binary());
```

Then we can define constraints (7.22) and (7.23) simply using the *Expr. sum* operator, that allows to sum the elements of an expression (in this case a the variable itself) along arbitrary dimensions. The code reads:

```
//each value only once per dimension
for (int d = 0; d < m; d++)
    M.Constraint(Expr.Sum(x, d), Domain.EqualsTo(1.0));</pre>
```

The last set of constraints (7.24), i.e. the sum over block, needs a little more effort: we must loop over all blocks and select the proper slice:

To set the triplets given in the set F we can use the Variable.pick method that returns a one dimensional view of an arbitrary set of elements of the variable.

```
M.Constraint(x.Pick(fixed_cells), Domain.EqualsTo(1.0));
```

SUDOKU: the complete example code.

The complete code for the SUDOKU problem is shown in Listing 7.16.

7.7. SUDOKU 77

Listing 7.16: Fusion implementation to solve SUDOKU.

7.8 Multi-processors Scheduling

In this case of study we consider a simple scheduling problem in which a set of jobs must be assigned to a set of identical machines. We want to minimize the makespan of the overall processing, i.e. the latest machine termination time.

The main aims of this case study are

- show how to define a Integer Linear Programming model,
- take advantage of Fusion operators to compactly express set of constraitns,
- provide to the solver an incumbent integer feasible solution.

Mathematical formulation

We are given a set of jobs J with |J| = n to be assigned to a set M of identical machines with |M| = m. Each job $j \in J$ has a processing time $T_j > 0$ and can be assigned to any machine. Our aim is to find the job scheduling that minimizes the overall makespan, i.e. the maximum complation time among all machines.

Formally, we introduce a binary variable x_{ij} that takes value one if the job j is assigned to the machine i, zero otherwise. The only constraint we need to set is the requirement that a job must be assigned to a single machine. The optimization model takes the following form:

Model (7.26) can be easily transformed in an integer linear programing model as the following

$$\min t$$
s.t.
$$\sum_{i \in M} x_{ij} = 1 \qquad j \in J$$

$$t \ge \sum_{j \in J} T_j x_{ij} \qquad i \in M$$

$$x_{ij} \in \{0, 1\} \qquad \forall i \in M, j \in J.$$
(7.27)

The implementation of this model in *Fusion* is straightforward:

```
Model M= new Model("Multi-processor scheduling");

Variable x= M.Variable("x", new int[]{m, n}, Domain.Binary());

Variable t= M.Variable("t",1, Domain.Unbounded());

M.Constraint( Expr.Sum(x,0), Domain.EqualsTo(1.0));

M.Constraint( Expr.Sub( Var.Repeat(t,m), Expr.Mul(x,T)) , Domain.GreaterThan(0.0));

M.Objective( ObjectiveSense.Minimize, t );
```

Most of the code is self-explaining. The only critical point is

```
M.Constraint( Expr.Sub( Var.Repeat(t,m), Expr.Mul(x,T)) , Domain.GreaterThan(0.0));
```

that implements the set of constraints

$$t \ge \sum_{j \in I} T_j x_{ij} \quad i \in M$$

To fit in Fusion we restate the constraints as

$$t - \sum_{j \in J} T_j x_{ij} \ge 0 \quad i \in M$$

which corresponds in matrix form to

$$t\mathbf{1} - xT \ge 0. \tag{7.28}$$

The function Var.repeat creates a vector of length m, which is what is stated in (7.28). The same results can be obtained as matrix multiplication, i.e. using Expr.mul, but in this particular case Var.repeat is faster as it does only a logical operation.

Longest Processing Time first rule (LPT)

The multiprocessor scheduling is known to be an NP-complete problem (see $\lceil GJ79 \rceil$). Neverthless there are effective heuristics, with proven worst case bound, that are able to provided a good integer solution quickly. In particular, we will use the so-called *Longest Processing Time first* rule (LPT, proposed in $\lceil Gra69 \rceil$).

The informal algorithm sketch is the following:

- while M is not empty do
 - let ${\tt k}$ the machine with the smallest load so far
 - let i be the job in M with the longest completion time
 - assign job i to machine k
 - update machine k load
 - remove i from M

This simple algorithm is a 1/3(4-1/m) approximation. So for m=1 we get the optimal solution (indeed there is no choices with a single machine); for $m \to \infty$ the approximation tends to its worst case of 4/3 (againg see [Gra69]).

A simple implementation is given below.

```
double [] init = new double[n*m];
double [] schedule= new double[m];

for(int i=0;i<n;i++)
{
   int next=0;
   for(int j=1;j<m;j++)
      if(schedule[j]<schedule[next]) next=j;

   schedule[next] += T[i];
   init[next*n + i] = 1;
}</pre>
```

An efficient implementation of the LPT rule is beyond the scope of this section. The important is that the scheduling produced by the LPT algorithm can be used as incumbent solution for the **MOSEK** mixed-integer linear programming solver. The availability of an integer feasible solution can significantly improve the performance of the solver.

To input the solution we only need to use the Variable.setLevel method, as shown below

```
x.SetLevel(init);
```

The effect of the availability of an incumbent solution can be easily seen looking at the solver output.

For instance, let's consider the following input

Running MOSEK the solution is the following

```
initial solution:
M 0 [1, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, ]
M 1 [0, 1, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1, 0, ]
M 2 [0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1, ]
M 3 [0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, ]
MOSEK solution:
M 0 [1, 0, 1, 0, 0, 1, 1, 0, 0, 0, 1, 0, 0, 0, 0, ]
M 1 [0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, ]
M 2 [0, 0, 0, 1, 1, 0, 0, 0, 1, 0, 0, 1, 0, 0, 0, ]
M 3 [0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1, 0, 0, ]
```

The running is very short. Without initial solution it much higher.

The complete code follows.

Listing 7.17: Complete code for LPT scheduling example.

                   for(int y=0; y<n;y++)</pre>
                       double value = x.Index(i,y).Level()[0];
                        Console.Write( "{0}, ", (int)value);
                   Console.WriteLine("]");
              }
              catch(SolutionError e)
                 //must do something about....
        }
    }
 }
}
```

7.9 Traveling Salesman Problem (TSP)

The *Traveling Salesman Problem* is one of the most famous and studied problem in combinatorics and integer optimization.

The main purpose of this case studies is to:

- show how to compactly define a model with Fusion;
- implement an iterative algorithm that solves a sequence of optimization problems;
- modify an optimization problem by additional constraints;
- accessing the solution of an optimization problem.

The material presented in this section draws inspiration from [Pat03].

We are given a directed graph G = (N, A), where N is the set of nodes and A is the set of arcs. To each arc $(i, j) \in A$ corresponds a nonnegative cost c_{ij} . We aim to find a tour on G, i.e. a path touching all nodes only once, with minimum cost. For example let's consider the simple graph in Fig. 7.3.

That corresponds to following adjacency and cost matrices A and c respectively:

$$A = \begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix} \quad c = \begin{bmatrix} 0 & 1 & 0.1 & 0.1 \\ 0.1 & 0 & 1 & 0 \\ 0 & 0.1 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

Typically, the problem is modelled introducing a set of binary variables x_{ij} such that

$$x_{ij} = \begin{cases} 0 & \text{if arc } (i,j) \text{ is in the tour} \\ 1 & \text{otherwise.} \end{cases}$$

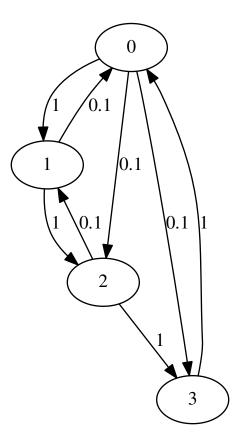

Fig. 7.3: A TSP example.

TSP is based on a simple assignement model:

min
$$\sum_{i < j} c_{ij} x_{ij}$$

 $\sum_{i} x_{ij} = 1 \quad \forall j = 1, \dots, n$
 $\sum_{j} x_{ij} = 1 \quad \forall i = 1, \dots, n$
 $x_{ij} \in \{0, 1\} \quad \forall i, j$ (7.29)

Problem (7.29) can be easily implemented in *Fusion*:

```
Model M = new Model();

Variable x = M.Variable(new int[]{n,n}, Domain.Binary());

M.Constraint( Expr.Sum(x,0), Domain.EqualsTo(1.0));
M.Constraint( Expr.Sum(x,1), Domain.EqualsTo(1.0));

M.Objective(ObjectiveSense.Minimize, Expr.Dot( C ,x) );
```

Note in particular how:

- we can sum over rows and/or column using the Expr. sum function;
- we can use Expr.dot to compute the objective function.

Solving problem (7.29) will not yield a valid TSP, but only ensure the path will pass only once through each node. It can be shown that the solution of problem (7.29) actually is composed by a set of node disjoined sub-tours. In our example we get the solution depicted in Fig. 7.4.

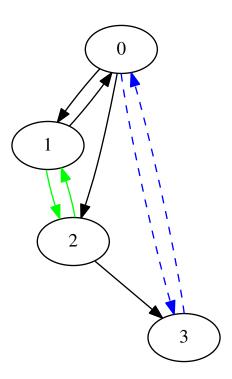

Fig. 7.4: Infeasible TSP solution: it has two disjoint loops.

i.e. there are two loops, namely $\theta -> 3 -> \theta$ and 1 -> 2 -> 1.

To obtain a solution to the TSP, we need some more constraints. One of the classical approach is the so-called *subtour elimination*: give a solution of (7.29) that is composed by at least two subtours, we add constraints that explicitly avoid that subtours:

$$\sum_{(i,j)\in c} x_{ij} \le |c| - 1 \quad \forall c \in C \tag{7.30}$$

Thus the problem we want to solve at each step is

$$\min \sum_{i < j} c_{ij} x_{ij}
\sum_{i} x_{ij} = 1 \qquad \forall j = 1, \dots, n
\sum_{j} x_{ij} = 1 \qquad \forall i = 1, \dots, n
x_{ij} \in \{0, 1\} \qquad \forall i, j
\sum_{(i,j) \in c} x_{ij} \le |c| - 1 \quad \forall c \in C$$

$$(7.31)$$

The overall scheme is the following:

- 1. set C as the empty set
- 2. solve problem (7.31)
- 3. **if** x has only one cycle **stop**
- 4. **else** add cycles to C and **goto** 2

Cycle detection is a fairly easy task. We omit the procedure here for sake of simplicity. We only assume that as results we obtain a list of cycles C, each one listing the arcs it is composed by.

Now we need to add a constraint for for each cycle. Since we have the list of arcs, and each one corresponds to a variable x[i][j], we can use the arc list and the function Variable.pick to define compactly constraints of the form (7.30)

```
foreach(ArrayList c in cycles)
{
   int [,] cc = new int[c.Count,2];
   int i=0;
   foreach( int[] a in c)
   {
      cc[i,0]= a[0];
      cc[i,1]= a[1];
      i++;
   }
   M.Constraint( Expr.Sum(x.Pick(cc)), Domain.LessThan( 1.0 * c.Count -1 ) );
}
```

Executing our procedure will yield the following output

```
it #1 - solution cost: 2.200000

cycles:
[0,3] - [3,0] -
[1,2] - [2,1] -

it #2 - solution cost: 4.000000

cycles:
[0,1] - [1,2] - [2,3] - [3,0] -

solution:
0 1 0 0
0 0 1 0
0 0 0 1
1 0 0 0
```

Thus we first discover the two cycle solution we knew; then the second iteration is forced not to include those cycles, and a new solution is located. This time it is composed by one loop, and as expected the cost is higher. The solution is depicted in Fig. 7.5.

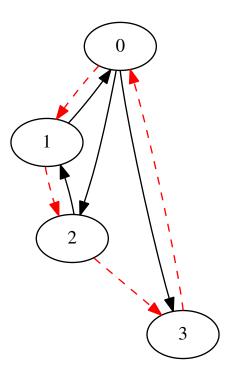

Fig. 7.5: The solution of the TSP example.

Formulation (7.31) can be improved in some cases exploiting the graph structure. Some simple tricks follow.

Self-loops

In case the graph contains self-loops, they are of no interest. Typically self-loop removal relies either on the definition of huge costs on that arcs or on the subtours elimination. Despite this works in practice, it is more advisable to just fix the corresponding variables to zero, i.e.

$$x_{ii} = 0 \quad \forall i = 1, \dots, n \tag{7.32}$$

These constraints will remove not only redundant variables, but also avoid unecessary large coefficients that can negatively affect the solver.

Constraints (7.32) are easily implemented as follows:

Two-arc loops removal

Assuming that we want to work on networks with more than two nodes, then it is reasonable to remove loops composed by only two arcs. This kind of loops are simple to define and come in reasonable number.

The constraints we need to add are

$$x_{ij} + x_{ji} \le 1 \quad \forall i, j = 1, \dots, n \tag{7.33}$$

Constraints (7.33) are easily implemented as follows:

```
M.Constraint( Expr.Add( x, x.Transpose()), Domain.LessThan(1.0));
```

Forcing graph topology

In many application the graph is actually quite sparse, as for instance if it is a road network. For this reason many x_{ij} 's can be fixed to zero. Defining A as the adjacency matrix of G, then we can just force the following constraints

$$x_{ij} \le A_{ij} \quad \forall i, j = 1, \dots, n \tag{7.34}$$

Constraints (7.34) translate in Fusion as:

```
M.Constraint(x, Domain.LessThan(A));
```

The complete working example

The complete code follows in Listing 7.18.

Listing 7.18: The complete code for the TSP examples.

```
using System;

      for(int j=0;j<n;j++)</pre>
      {
        try
          if (x.Level()[i*n+j] \le 0.5) continue;
        catch(SolutionError e){}
        bool found = false;
        foreach(ArrayList c in cycles)
          foreach(int[] a in c)
            if( i == a[0] || j == a[0] ||
                i == a[1] || j == a[1] )
              c.Add( new int[]{i,j} );
              found = true;
              break;
          if(found==true) break;
        }
        if(found!=true)
          ArrayList ll= new ArrayList();
```

```
11.Add( new int[]{i,j} );
                  cycles.Add(11);
              }
            }
            Console.WriteLine("\ncycles:");
            foreach(ArrayList c in cycles)
              foreach(int[] a in c)
                Console.WriteLine("[{0},{1}] - ",a[0],a[1]);
              Console.Write("\n");
            if(cycles.Count == 1) break;
            foreach(ArrayList c in cycles)
              int [,] cc = new int[c.Count,2];
              int i=0;
              foreach( int[] a in c)
                cc[i,0]= a[0];
                cc[i,1] = a[1];
                i++;
              }
              M.Constraint( Expr.Sum(x.Pick(cc)), Domain.LessThan( 1.0 * c.Count -1 ));
          }
          try
          {
            Console.WriteLine("\nsolution:");
            for(int i=0;i<n;i++)</pre>
              for(int j=0;j<n;j++)</pre>
                Console.Write(" {0} ", ((int) x.Level()[i*n + j]) );
              Console.Write("\n");
            }
          }
          catch(SolutionError e){}
     }
   }
 }
}
```

INTERACTION WITH THE SOLVER

The *Model* class is the interface to the solver for that specific model. When a *Model* class is instantiated, the solver environment is created.

Through the Model methods the user can retrieve information from the solver as:

• last execution/solution status

and set options about

- algorithm selection
- algorithm tolerances and stopping criteria
- input/output format options for the input/output operation.

The Fusion API provides the most commonly used solver functionality and options. If some advanced functionalities are needed, low level access t othe solver can be obtained from the model, see Section 8.4.

Additional issues:

- how to stop the solver when key-pressed CTRL+C is not available is covered in Section 8.5.
- it is possible to use call-back, thoght some limitations apply: see 8.6.

Section index:

8.1 Solver Parameters

MOSEK comes with a large number of parameters that allows the user to tune its behavior. In *Fusion*, parameters can be set using the method *Model.setSolverParam*. Each parameter is identified by a unique string and accept either integers, floating point values or symbolic strings. *Fusion* tries to convert the value given by the user to the relevant type for the parameter.

If the conversion fails, an exception of type FusionException is thrown. Therefore it is always a good idea to incapsulate code setting parameters by an exception-catching block.

A complete reference of the parameters is available in Section 13.4.

Real and Integer Parameters

These parameters can be specified both as a numerical type or a string. Fusion will cast the input to the desired type.

For instance a real parameter as optimizerMaxTime, the command

```
M.SetSolverParam("optimizerMaxTime", 100.0);
```

would have the same effect as

```
M.SetSolverParam("optimizerMaxTime", 100);
```

or

```
M.SetSolverParam("optimizerMaxTime", "100.0");
```

On the other hand,

```
M.SetSolverParam("optimizerMaxTime", "100 s.");
```

will fail throwing an exception of type FusionException.

String and Symbolic Parameters

These parameters accept strings, and therefore any other data type is not accepted.

Some parameters accept symbolic strings. For instance the parameter *presolveUse* accept a string among on, msk:const:off, free:

```
M.SetSolverParam("presolveUse", "off");
```

Any other string will not be accepted.

8.2 Problem and Solution Status

Once the solver terminates, it is time to check the results. The solver provides two different statuses that the user can inquery upon:

- solution status: information about the solution optimality degreee (optimal, nearly-optimal,...)
- problem status: information about the problem itseelf (feasibility, unboundness,...)

It is of the utmost importance to be able to fully understand the statuses that can be returned by the solver.

8.2.1 Solution Status

In principle, the only meaningful solution the user should care for is the optimal one. When it is not available the solver should have issued an infeasibility certificate. This behavior is clearly overoptimistic: for instance the solver might have been stopped by a time limit reached, or the execution stalled just before optimality had been reached. For this reason **MOSEK** actually distinguishes several solution statuses, some being

- optimal (Optimal)
- near optimal (NearOptimal)
- unknown (Unknown)

The complete list is available SolutionStatus. After MOSEK terminates, users should check the solution status using the functions Model.getPrimalSolutionStatus and Model.getDualSolutionStatus. Depending on that status the user can decide the action to be taken. Often a suboptimal solution is still valuable and deserve attention.

When a solution is recovered from a *Variable* object, it is only available if its status is among those considered *acceptable*. Otherwise an exception of type *SolutionError* is thrown.

It is therefore a good practice to

• protect the code against such exceptions

• investigate the reasons whenever they happens.

By default, acceptable status is <code>NearOptimal</code>. This can be changed using the function <code>Model.acceptedSolutionStatus</code>. For instance, if we want to accept every solution which is at least feasible we may write

```
M.AcceptedSolutionStatus(fusion.AccSolutionStatus.Feasible);
```

while with

```
M.AcceptedSolutionStatus(AccSolutionStatus.Anything);
```

we accept all available solutions.

Important: It is a user responsibility to check the actual solution quality.

To enquiry about the solution status accepted by a given Model instance just say

```
AccSolutionStatus accsolstat = M.GetAcceptedSolutionStatus();
```

8.2.2 Problem Status

The problem status is mainly concerned about whether the given optimization model is feasible. **MOSEK** is able to certified the infeasibility of conic problems up to a certain degree of numerical accuracy. The problem status can be checked using the <code>Model.getProblemStatus</code>.

Once the optimization terminates, it is good practice to inspect the results not only in terms of solution status, but also to check whether the problem has been certified feasible. In particular, if the solution status is not optimal, then the problem may be infeasible. To check for infeasibility we may write

```
switch( M.GetProblemStatus(SolutionType.Interior) )
{
case ProblemStatus.PrimalAndDualFeasible:
case ProblemStatus.PrimalFeasible:
case ProblemStatus.DualFeasible:
   /*Here I should get the solution....*/
   break;
default:
   break;
}
```

8.2.3 Accessing Solution Values

If a solution has been accepted, we can query for the objective function value for the primal and dual problems. They are readly available by the <code>Model.primalObjValue</code> and <code>Model.dualObjValue</code>, respectively.

Values attained by variables and constraints are available by the *Variable.level* method in classes *Variable* and *Constraint*, respectively: *Fusion* returns a flat array of values that the user can afterwards reshape.

In the same way users can access the corresponding dual values for variables and constraints, using the <code>Constraint.dual</code> method.

8.3 Input/Output

Through the *Model* class users can also control the solver I/O. This includes:

8.3. Input/Output 95

- Execution logging
- Pretty printing
- Dump problem to disk.

8.3.1 Logging

By default the solver runs silently and does not produce any output. In fact the output is discarded. However, the output of the solver can be redirected to any output stream using the method <code>Model.setLogHandler</code>. For instance, we can use the standard output

```
M.SetLogHandler(Console.Out);
```

A stream can be detached by passing NULL.

8.3.2 Pretty Printing

Fusion includes pretty printing for variables, matrices, expressions and constraints: a call to the method toString() returns a plain text representation of the object. This is particularly useful during development when one need to debug models and make sure that the model that has been defined is what it is meant to be.

In general, Fusion prints

- object type
- size and dimension
- a human readable representation

In general, a sparse representation of any object is printed whenever possible.

Warning: Pretty printing of too large models is most likely unreadable!

Specific information follows.

fusion. Variable

A compact textual representation can be easily obtained: for instance a one dimensional variable called x will be printed just saying

```
int n = 4;
Variable x = M.Variable("x",n, Domain.GreaterThan(0.0));
Console.WriteLine( x.ToString() );
```

with the following output

```
LinearVariable(('x',4))
```

fusion. Matrix

Matrices are printed either in dense row-wise form or sparse triplet form. For instance, given a 2×4 matrix filled with ones, we can print it out as

```
Console.WriteLine( Matrix.Ones(2,4).ToString());
```

producing the following output

```
DenseMatrix(2,4: [ 1.0,2.0,3.0,4.0 ],[ 5.0,6.0,7.0,8.0 ])
```

For a sparse matrix, for instance the identity

```
Console.WriteLine( Matrix.Eye(4).ToString());
```

we get

```
SparseMatrix(4,4, [(0,0,1.0),(1,1,1.0),(2,2,1.0),(3,3,1.0)])
```

fusion. Expression

Expressions are organized as matrices, and they share the overall layout. In particular, expressions are printed in sparse format. For instance

```
Variable x = M.Variable("x", 4, Domain.Unbounded());
Expression ee = Expr.Mul(Matrix.Eye(4), x);
Console.WriteLine(ee.ToString());
```

It will produce the following output

In this case the expression is stored as a one dimensional array. The following case shows what happens with sparsity: we multipy element-wise the identity matrix times a bi-dimensional squared variable, i.e.

```
Variable x = M.Variable("x", new int[]{4,4},Domain.Unbounded());
Expression ee = Expr.MulElm(Matrix.Eye(4), x);
Console.WriteLine(ee.ToString());
```

It will produce the following output

```
Expr(ndim=(4,4),

[ ([0 0]) -> + 1.0 X[0,0],

([1 1]) -> + 1.0 X[1,1],

([2 2]) -> + 1.0 X[2,2],

([3 3]) -> + 1.0 X[3,3] ])
```

As expected the result is a squared matrix of the same dimension, but only the non zeros entries are printed.

fusion.Constraint

A compact representation a the constraint can be obtain using the Constraint.toString. For instance a set of linear constraints of the form Ix = 0, with I being the identity matrix is implemented can be visualize as

```
int n = 4;
Variable x = M.Variable("x",n, Domain.GreaterThan(0.0));
Constraint c = M.Constraint("c", Expr.Mul(Matrix.Eye(n),x), Domain.EqualsTo(0.0));
Console.WriteLine(c.ToString());
```

8.3. Input/Output 97

The output is

```
Constraint( 'c', (4),

c[0]: +1.0 x[0] = 0.0,

c[1]: +1.0 x[1] = 0.0,

c[2]: +1.0 x[2] = 0.0,

c[3]: +1.0 x[3] = 0.0)
```

Notice that only non zero entries are printed.

The printed representation also includes all auxiliary variables introduced by Fusion. For instance a single second order cone of the form

8.3.3 Dumping a Problem to File

A model can be dump to file using the <code>Model.writeTask</code>, just specifying the file name. The file type will be deduced automatically by the extension. For instance

```
M.WriteTask("dump.mps");
```

will dump the model to an MPS file. Supported formats are listed in Section 14.

All format can be gripped appending the .gz extension, i.e. the command

```
M.WriteTask("dump.mps.gz");
```

will produce an MPS file compressed in gzipped format.

Warning: The dumped model also contains all the additional variables generated when defining cones.

It is therefore advisable to assign meaningful names to variables when debugging, in order to improved readibility.

For more details please refer to Section 14.

8.4 Access to Optimizer API Task

The <code>Model</code> class acts as a tiny wrapper on top of a **MOSEK** task. Some low-level functionalities provided by the task in the optimizer API are not directly supported by <code>Fusion</code>. Instead, the task handler can be obtained by the method <code>Model.getTask</code>.

Warning: The task handler is **not** a copy and any modification may invalidate or corrupt the model.

Therefore the access to the task should be considered carefully and avoided unless special functionalities are required.

8.5 Stopping the Solver Execution

To force **MOSEK** to stop, *Fusion* class *Model* provides the method *Model.breakSolver* that notifies the solver that it must stop as soon as possible. The solver periodically test for such notification and as it happens, it will stop the execution. The state of the solver and solution may be undefined (see Section 8.2).

Note: The built-in stopping criteria should be used instead whenever possible!

The typical steps are the following:

- 1. build the optimization model (say M) as usual;
- 2. create a separate task in which M will run;
- 3. once the termination criterion is met call the function Model.breakSolver on M.

Warning: These steps are very language dependent and particular care must be taken to avoid stalling or other undesired side effects.

8.5.1 A Working Example: Setting a Time Limit

In this example we will use a time limit as an additional stopping criterion, despite the fact that a time limit is available as a parameter in **MOSEK**.

We will use a simple MIP model which we know it runs for quite long time

min
$$\sum_{i \in P_j} x_i$$

s.t. $\sum_{i \in P_j} x_i = 1$ $j = 1, ..., m$
 $x_i \in \{0, 1\}$ $j = 1, ..., n$

where P_j is a permutation of $\{1,\ldots,n\}$ such that $|P_j|=p$. This model is declared as

```
using (Model M = new Model("SolveBinary"))
{
    M.SetLogHandler(System.Console.Out);

    //Variable x = M.Variable("x", n, Domain.InRange(0,1));
    Variable x = M.Variable("x", n, Domain.Binary());
    M.Objective(ObjectiveSense.Minimize, Expr.Sum(x));
    //M.SetSolverParam("numThreads",1);

int[] idxs = new int[n]; for (int i = 0; i < n; ++i) idxs[i] = i;
    int[] cidxs = new int[p];

for (var i = 0; i < m; ++i)
    {
        nshuffle(R,idxs,p);
        Array.Copy(idxs,cidxs,p);
        M.Constraint(Expr.Sum(x.Pick(cidxs)),Domain.EqualsTo(p / 2));
    }
}</pre>
```

Once the model has been built, we proceed creating a new thread that will be responsible for the actual solver execution:

```
var T = new Thread(new ThreadStart(B.run));
T.Start();
```

Then in the main thread we can check for the criterion to be satisfied

- a time limit of five seconds
- the user pressing CTRL+C

It must be notice that we need to ensure that the execution on the main threads resumes after the solver actually terminates, i.e. the auxiliary threads returns. This is performed by the following lines:

```
Stopwatch w = new Stopwatch(); w.Start();
while (! stop)
{
    if (w.ElapsedMilliseconds > timeout*1000)
        {
        Console.WriteLine("Solver terminated due to timeout!");
        M.BreakSolver();
        break;
    }
}
```

The complete source code follows in Listing 8.1.

Listing 8.1: Example on how stop solver execution.

```
using System;
using System. Threading;
using mosek.fusion;
using System.Diagnostics;
namespace mosek
 namespace fusion
   namespace example
      public class Breaker
        Model M;
       long timeout;
        bool stop;
        public Breaker(Model _M,long _timeout) { M = _M; timeout = _timeout; stop = false; }
        public void stopThread() { stop = true; }
        public void run()
          Stopwatch w = new Stopwatch(); w.Start();

                  Array.Copy(idxs,cidxs,p);
                  M.Constraint(Expr.Sum(x.Pick(cidxs)),Domain.EqualsTo(p / 2));
              var B = new Breaker(M, timeout);
              var T = new Thread(new ThreadStart(B.run));
              T.Start():
              M.Solve():
              B.stopThread();
              T.Join();
              Console.WriteLine("End.");
        }
     }
   }
 }
}
```

8.6 Callbacks in Fusion

Callbacks are a very useful mechanism to interact with the solver at runtime and modify its behaviour. Fusion provides a limited support for callback that allows the user to hook a function to the solver progress callback. This entry point is regularly called during the optimization and can be used to

- obtain a customized log of the solver execution,
- $\bullet\,$ collect information for debugging purpose or
- ask the solver to terminate.

Important: The only function that can be called from the callback is the *Model.breakSolver*, indicating that the solver should terminate. No other functions *must* be called from the callback. Otherwise the execution state of the solver and its outcome are undefined.

The callback can be set calling the Model.setCallbackHandler method.

Note: For compatibility reason the callback must return an integer value, though that value is actually ignored.

8.6.1 A minimal Working Example

The following example is based on the basic tutorial in Section 4.1. It is extended providing the solver with a callback funtion that print out additional output during the optimization algorithm execution. The output depends on the eleted algorithm (primal/dual simplex or innterio-point). Moreover, the execution is terminated when a given time limit is reached.

```
class myCallback : mosek.DataCallback
  double maxtime;
 Model M;
 public myCallback( double maxtime_,
                     Model M_)
     maxtime = maxtime_;
     M = M_{:}
    }
 public override int callback( callbackcode caller,
                                double[]
                                             douinf.
                                             intinf.
                                int[]
                                long[]
                                             lintinf )
    {
     double opttime = 0.0;
      int itrn;
     double pobj, dobj, stime;
      switch (caller)
      case callbackcode.begin_intpnt:
        Console.WriteLine("Starting interior-point optimizer");
        break:
      case callbackcode.intpnt:
               = intinf[(int) iinfitem.intpnt_iter
        itrn
                = douinf[(int) dinfitem.intpnt_primal_obj];
        pobi
                = douinf[(int) dinfitem.intpnt_dual_obj ];
        stime = douinf[(int) dinfitem.intpnt_time
                                                         ];
        opttime = douinf[(int) dinfitem.optimizer_time
        Console.WriteLine("Iterations: {0,-3}",itrn);
        Console.WriteLine(" Elapsed: Time: {0,6:F2}({1:F2})",opttime,stime);
        Console.WriteLine(" Primal obj.: {0,-18:E6} Dual obj.: {1,018:E6}e",pobj,dobj);
        break;
      case callbackcode.end_intpnt:
        Console.WriteLine("Interior-point optimizer finished.");
      case callbackcode.begin_primal_simplex:
        Console.WriteLine("Primal simplex optimizer started.");
      case callbackcode.update_primal_simplex:
               = intinf[(int) iinfitem.sim_primal_iter ];
        itrn
                = douinf[(int) dinfitem.sim_obj
                                                         ];
        pobj
                                                         ];
                = douinf[(int) dinfitem.sim_time
        stime
        opttime = douinf[(int) dinfitem.optimizer_time
        Console.WriteLine("Iterations: {0,-3}}", itrn);
```

```
Console.WriteLine("
                             Elapsed time: \{0,6:F2\}(\{1:F2\})", opttime, stime);
        Console.WriteLine(" Obj.: {0,-18:E6}", pobj );
      case callbackcode.end_primal_simplex:
        Console.WriteLine("Primal simplex optimizer finished.");
      case callbackcode.begin_dual_simplex:
        Console.WriteLine("Dual simplex optimizer started.");
        break:
      case callbackcode.update_dual_simplex:
        itrn
                = intinf[(int) iinfitem.sim_dual_iter
                                                          ];
                = douinf[(int) dinfitem.sim_obj
                                                          ];
                                                         ];
        stime = douinf[(int) dinfitem.sim_time
        opttime = douinf[(int) dinfitem.optimizer_time
        Console.WriteLine("Iterations: {0,-3}}", itrn);
        Console.WriteLine(" Elapsed time: {0,6:F2}({1:F2})",opttime,stime);
        Console.WriteLine(" Obj.: {0,-18:E6}", pobj );
        break:
      case callbackcode.end_dual_simplex:
        Console.WriteLine("Dual simplex optimizer finished.");
        break;
      case callbackcode.begin_bi:
        Console.WriteLine("Basis identification started.");
        break:
      case callbackcode.end_bi:
       Console.WriteLine("Basis identification finished.");
        break:
      default:
       break:
      if (opttime >= maxtime)
        Console.WriteLine("MOSEK is spending too much time. Terminate it.");
       M.BreakSolver();
      }
      return 0;
    }
}
```

The callback function is then simply hooked:

```
M.SetCallbackHandler( new myCallback(maxtime, M) );
```

The complete working example follows in Listing 8.2.

Listing 8.2: Example of callback function with *Fusion*.

```

    File:
//
                callback.cs
//
//
                To demonstrate how to use the progress
    Purpose:
//
                callback.
//
                Use this script as follows:
//
                callback psim
//
                callback dsim
//
                callback intpnt
                The first argument tells which optimizer to use
                i.e. psim is primal simplex, dsim is dual simplex
```

```
and intpnt is interior-point.

        }
}
```

PERFORMANCE CONSIDERATIONS

9.1 Sparse Matrices

Deciding whether a matrix should be stored in dense or sparse format is not always trivial and it does not only depend on storage considerations. For a given $n \times m$ matrix with l non zero entries, the storage required is proportional to

- $n \cdot m$ for a dense matrix,
- $3 \cdot l$ for a sparse matrix.

Therefore if $l \ll n \cdot m$, then the required storage in sparse form is much smaller than in dense format. The consequences are

- reduced memory requirements,
- faster expression computation,
- ullet meet the internal solver representation.

However, there are borderline cases in which these advantages may vanish due to overhaed on creating the triplets representation.

Sparsity is a key feature of many optimization models and happens often naturally. For instance, linear constraints arising from networks or multi-period planning are typically sparse. Fusion does not detect sparsity but leaves to the user the responsibility to choose the most appropriate storage format. It provides adaptors for sparse matrices by Matrix static methods such as Matrix. sparse or Matrix. diag.

9.2 Nested Expressions

A possible source of performance degradation is an excessive use of nested expressions. For example

$$\sum_{i=1}^{n} A_i x_i$$

$$x_i \in \mathbb{R}^k, A_i \in \mathbb{R}^{k \times k},$$

it could be expressed in a loop as

```
ee = Expr.constTerm(k, 0.)
for i in range(n):
    ee = Expr.add( ee, Expr.mul(A[i],x[i] ) )
```

A better way is to store intermediate expressions for $A_i x_i$ and sum all of them in one step:

```
Exp.add( [ Expr.mul(AA,xx) for (AA,xx) in zip(AA,xx)] )
```

This implementation is more efficient as it reduces the number of intermediate expressions.

9.3 Names

Fusion makes very easy to specify names for variables, constraints and the objective function. It is very useful for debugging and improves the readability of problems stored in files. But unfortunately it comes at a price:

 \bullet Fusion must check and make sure that names are unique

To reduce the overhead, names are actually generated when some operation explicitly ask for them. For example, if we want to print a variable information with the following code

```
x = m.variable("x", 10, Domain.unbounded())
print(x.toString())
```

with the following output

Fusion generates unique names for the x entries when Variable. toString is called.

To optimize performances it is therefore advisable to not specify names at all. Notice that a careful choice of variable names makes the code very readable with no needs for labels.

PROBLEM FORMULATION AND SOLUTIONS

In this chapter we will discuss the following issues:

- The formal definitions of the problem types that MOSEK can solve.
- The solution information produced by MOSEK.
- The information produced by MOSEK if the problem is infeasible.

10.1 Linear Optimization

A linear optimization problem can be written as

where

- m is the number of constraints.
- \bullet *n* is the number of decision variables.
- $x \in \mathbb{R}^n$ is a vector of decision variables.
- $c \in \mathbb{R}^n$ is the linear part of the objective function.
- $A \in \mathbb{R}^{m \times n}$ is the constraint matrix.
- $l^c \in \mathbb{R}^m$ is the lower limit on the activity for the constraints.
- $u^c \in \mathbb{R}^m$ is the upper limit on the activity for the constraints.
- $l^x \in \mathbb{R}^n$ is the lower limit on the activity for the variables.
- $u^x \in \mathbb{R}^n$ is the upper limit on the activity for the variables.

A primal solution (x) is (primal) feasible if it satisfies all constraints in (10.1). If (10.1) has at least one primal feasible solution, then (10.1) is said to be (primal) feasible.

In case (10.1) does not have a feasible solution, the problem is said to be (primal) infeasible

10.1.1 Duality for Linear Optimization

Corresponding to the primal problem (10.1), there is a dual problem

maximize
$$(l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x + c^f$$

$$A^T y + s_l^x - s_u^x = c,$$
subject to
$$-y + s_l^c - s_u^c = 0,$$

$$s_l^c, s_u^c, s_l^x, s_u^x \geq 0.$$
 (10.2)

If a bound in the primal problem is plus or minus infinity, the corresponding dual variable is fixed at 0, and we use the convention that the product of the bound value and the corresponding dual variable is 0. E.g.

$$l_i^x = -\infty \quad \Rightarrow \quad (s_l^x)_j = 0 \text{ and } l_i^x \cdot (s_l^x)_j = 0.$$

This is equivalent to removing variable $(s_l^x)_j$ from the dual problem. A solution

$$(y, s_{l}^{c}, s_{u}^{c}, s_{l}^{x}, s_{u}^{x})$$

to the dual problem is feasible if it satisfies all the constraints in (10.2). If (10.2) has at least one feasible solution, then (10.2) is (dual) feasible, otherwise the problem is (dual) infeasible.

A Primal-dual Feasible Solution

A solution

$$(x, y, s_l^c, s_u^c, s_l^x, s_u^x)$$

is denoted a *primal-dual feasible solution*, if (x) is a solution to the primal problem (10.1) and $(y, s_l^c, s_u^c, s_l^x, s_u^x)$ is a solution to the corresponding dual problem (10.2).

The Duality Gap

Let

$$(x^*, y^*, (s_l^c)^*, (s_u^c)^*, (s_l^x)^*, (s_u^x)^*)$$

be a primal-dual feasible solution, and let

$$(x^c)^* := Ax^*.$$

For a primal-dual feasible solution we define the *duality gap* as the difference between the primal and the dual objective value,

$$c^{T}x^{*} + c^{f} - \left\{ (l^{c})^{T}(s_{l}^{c})^{*} - (u^{c})^{T}(s_{u}^{c})^{*} + (l^{x})^{T}(s_{l}^{x})^{*} - (u^{x})^{T}(s_{u}^{x})^{*} + c^{f} \right\}$$

$$= \sum_{i=0}^{m-1} \left[(s_{l}^{c})_{i}^{*}((x_{i}^{c})^{*} - l_{i}^{c}) + (s_{u}^{c})_{i}^{*}(u_{i}^{c} - (x_{i}^{c})^{*}) \right]$$

$$+ \sum_{j=0}^{m-1} \left[(s_{l}^{x})_{j}^{*}(x_{j} - l_{j}^{x}) + (s_{u}^{x})_{j}^{*}(u_{j}^{x} - x_{j}^{*}) \right] \ge 0$$

$$(10.3)$$

where the first relation can be obtained by transposing and multiplying the dual constraints (10.2) by x^* and $(x^c)^*$ respectively, and the second relation comes from the fact that each term in each sum is nonnegative. It follows that the primal objective will always be greater than or equal to the dual objective.

An Optimal Solution

It is well-known that a linear optimization problem has an optimal solution if and only if there exist feasible primal and dual solutions so that the duality gap is zero, or, equivalently, that the *complementarity conditions*

$$\begin{array}{rclcrcl} (s_{u}^{c})_{i}^{*}((x_{i}^{c})^{*}-l_{i}^{c}) & = & 0, & i=0,\ldots,m-1, \\ (s_{u}^{c})_{i}^{*}(u_{i}^{c}-(x_{i}^{c})^{*}) & = & 0, & i=0,\ldots,m-1, \\ (s_{l}^{x})_{j}^{*}(x_{j}^{*}-l_{j}^{x}) & = & 0, & j=0,\ldots,n-1, \\ (s_{u}^{x})_{j}^{*}(u_{j}^{x}-x_{j}^{*}) & = & 0, & j=0,\ldots,n-1, \end{array}$$

are satisfied.

If (10.1) has an optimal solution and **MOSEK** solves the problem successfully, both the primal and dual solution are reported, including a status indicating the exact state of the solution.

10.1.2 Infeasibility for Linear Optimization

Primal Infeasible Problems

If the problem (10.1) is infeasible (has no feasible solution), **MOSEK** will report a certificate of primal infeasibility: The dual solution reported is the certificate of infeasibility, and the primal solution is undefined.

A certificate of primal infeasibility is a feasible solution to the modified dual problem

such that the objective value is strictly positive, i.e. a solution

$$(y^*, (s_l^c)^*, (s_u^c)^*, (s_l^x)^*, (s_u^x)^*)$$

to (10.4) so that

$$(l^c)^T(s_l^c)^* - (u^c)^T(s_u^c)^* + (l^x)^T(s_l^x)^* - (u^x)^T(s_u^x)^* > 0.$$

Such a solution implies that (10.4) is unbounded, and that its dual is infeasible. As the constraints to the dual of (10.4) are identical to the constraints of problem (10.1), we thus have that problem (10.1) is also infeasible.

Dual Infeasible Problems

If the problem (10.2) is infeasible (has no feasible solution), **MOSEK** will report a certificate of dual infeasibility: The primal solution reported is the certificate of infeasibility, and the dual solution is undefined.

A certificate of dual infeasibility is a feasible solution to the modified primal problem

minimize
$$c^T x$$

subject to $\hat{l}^c \leq Ax \leq \hat{u}^c$, $\hat{l}^x \leq x \leq \hat{u}^x$, (10.5)

where

$$\hat{l}_i^c = \left\{ \begin{array}{ll} 0 & \text{if } l_i^c > -\infty, \\ -\infty & \text{otherwise,} \end{array} \right\} \quad \text{and} \quad \hat{u}_i^c := \left\{ \begin{array}{ll} 0 & \text{if } u_i^c < \infty, \\ \infty & \text{otherwise,} \end{array} \right\}$$

and

$$\hat{l}_{j}^{x} = \left\{ \begin{array}{ll} 0 & \text{if } l_{j}^{x} > -\infty, \\ -\infty & \text{otherwise,} \end{array} \right\} \quad \text{and} \quad \hat{u}_{j}^{x} := \left\{ \begin{array}{ll} 0 & \text{if } u_{j}^{x} < \infty, \\ \infty & \text{otherwise,} \end{array} \right\}$$

such that

$$c^T x < 0$$
.

Such a solution implies that (10.5) is unbounded, and that its dual is infeasible. As the constraints to the dual of (10.5) are identical to the constraints of problem (10.2), we thus have that problem (10.2) is also infeasible.

Primal and Dual Infeasible Case

In case that both the primal problem (10.1) and the dual problem (10.2) are infeasible, **MOSEK** will report only one of the two possible certificates — which one is not defined (**MOSEK** returns the first certificate found).

Minimalization vs. Maximalization

When the objective sense of problem (10.1) is maximization, i.e.

the objective sense of the dual problem changes to minimization, and the domain of all dual variables changes sign in comparison to (10.2). The dual problem thus takes the form

This means that the duality gap, defined in (10.3) as the primal minus the dual objective value, becomes nonpositive. It follows that the dual objective will always be greater than or equal to the primal objective. The primal infeasibility certificate will be reported by **MOSEK** as a solution to the system

$$A^{T}y + s_{l}^{x} - s_{u}^{x} = 0,$$

$$-y + s_{l}^{c} - s_{u}^{c} = 0,$$

$$s_{l}^{c}, s_{u}^{c}, s_{l}^{x}, s_{u}^{x} \leq 0,$$
(10.6)

such that the objective value is strictly negative

$$(l^c)^T(s_l^c)^* - (u^c)^T(s_u^c)^* + (l^x)^T(s_l^x)^* - (u^x)^T(s_u^x)^* < 0.$$

Similarly, the certificate of dual infeasibility is an x satisfying the requirements of (10.5) such that $c^T x > 0$.

10.2 Conic Quadratic Optimization

Conic quadratic optimization is an extension of linear optimization (see Section 10.1) allowing conic domains to be specified for subsets of the problem variables. A conic quadratic optimization problem can be written as

minimize
$$c^T x + c^f$$

subject to $l^c \le Ax \le u^c$,
 $l^x \le x \le u^x$,
 $x \in \mathcal{K}$, (10.7)

where set \mathcal{K} is a Cartesian product of convex cones, namely $\mathcal{K} = \mathcal{K}_1 \times \cdots \times \mathcal{K}_p$. Having the domain restriction, $x \in \mathcal{K}$, is thus equivalent to

$$x^t \in \mathcal{K}_t \subset \mathbb{R}^{n_t}$$
,

where $x = (x^1, ..., x^p)$ is a partition of the problem variables. Please note that the *n*-dimensional Euclidean space \mathbb{R}^n is a cone itself, so simple linear variables are still allowed.

MOSEK supports only a limited number of cones, specifically:

- The \mathbb{R}^n set.
- The quadratic cone:

$$Q^{n} = \left\{ x \in \mathbb{R}^{n} : x_{1} \ge \sqrt{\sum_{j=2}^{n} x_{j}^{2}} \right\}.$$

• The rotated quadratic cone:

$$Q_r^n = \left\{ x \in \mathbb{R}^n : 2x_1 x_2 \ge \sum_{j=3}^n x_j^2, \quad x_1 \ge 0, \quad x_2 \ge 0 \right\}.$$

Although these cones may seem to provide only limited expressive power they can be used to model a wide range of problems as demonstrated in [MOSEKApS12].

10.2.1 Duality for Conic Quadratic Optimization

The dual problem corresponding to the conic quadratic optimization problem (10.7) is given by

maximize
$$(l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x + c^f$$
 subject to
$$A^T y + s_l^x - s_u^x + s_n^x = c - y + s_l^c - s_u^c = 0,$$

$$s_l^c, s_u^c, s_l^x, s_u^x \ge 0,$$

$$s_n^x \in \mathcal{K}^*,$$
 (10.8)

where the dual cone \mathcal{K}^* is a Cartesian product of the cones

$$\mathcal{K}^* = \mathcal{K}_1^* \times \cdots \times \mathcal{K}_n^*$$

where each \mathcal{K}_t^* is the dual cone of \mathcal{K}_t . For the cone types **MOSEK** can handle, the relation between the primal and dual cone is given as follows:

• The \mathbb{R}^n set:

$$\mathcal{K}_t = \mathbb{R}^{n_t} \quad \Leftrightarrow \quad \mathcal{K}_t^* = \{ s \in \mathbb{R}^{n_t} : \quad s = 0 \}.$$

• The quadratic cone:

$$\mathcal{K}_t = \mathcal{Q}^{n_t} \quad \Leftrightarrow \quad \mathcal{K}_t^* = \mathcal{Q}^{n_t} = \left\{ s \in \mathbb{R}^{n_t} : s_1 \ge \sqrt{\sum_{j=2}^{n_t} s_j^2} \right\}.$$

• The rotated quadratic cone:

$$\mathcal{K}_t = \mathcal{Q}_r^{n_t} \quad \Leftrightarrow \quad \mathcal{K}_t^* = \mathcal{Q}_r^{n_t} = \left\{ s \in \mathbb{R}^{n_t} : 2s_1 s_2 \ge \sum_{j=3}^{n_t} s_j^2, \quad s_1 \ge 0, \quad s_2 \ge 0 \right\}.$$

Please note that the dual problem of the dual problem is identical to the original primal problem.

10.2.2 Infeasibility for Conic Quadratic Optimization

In case **MOSEK** finds a problem to be infeasible it reports a certificate of infeasibility. This works exactly as for linear problems (see Section 10.1.2).

Primal Infeasible Problems

If the problem (10.7) is infeasible, **MOSEK** will report a certificate of primal infeasibility: The dual solution reported is the certificate of infeasibility, and the primal solution is undefined.

A certificate of primal infeasibility is a feasible solution to the problem

$$\begin{array}{lll} \text{maximize} & (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x \\ \text{subject to} & & & & & & & & \\ & & & & & & & & & \\ & & & & & & & & & \\ & & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & & \\$$

such that the objective value is strictly positive.

Dual infeasible problems

If the problem (10.8) is infeasible, **MOSEK** will report a certificate of dual infeasibility: The primal solution reported is the certificate of infeasibility, and the dual solution is undefined.

A certificate of dual infeasibility is a feasible solution to the problem

where

$$\hat{l}_i^c = \left\{ \begin{array}{ll} 0 & \text{if } l_i^c > -\infty, \\ -\infty & \text{otherwise,} \end{array} \right\} \quad \text{and} \quad \hat{u}_i^c := \left\{ \begin{array}{ll} 0 & \text{if } u_i^c < \infty, \\ \infty & \text{otherwise,} \end{array} \right\}$$

and

$$\hat{l}_{j}^{x} = \left\{ \begin{array}{ll} 0 & \text{if } l_{j}^{x} > -\infty, \\ -\infty & \text{otherwise,} \end{array} \right\} \quad \text{and} \quad \hat{u}_{j}^{x} := \left\{ \begin{array}{ll} 0 & \text{if } u_{j}^{x} < \infty, \\ \infty & \text{otherwise,} \end{array} \right\}$$

such that the objective value is strictly negative.

10.3 Semidefinite Optimization

Semidefinite optimization is an extension of conic quadratic optimization (see Section 10.2) allowing positive semidefinite matrix variables to be used in addition to the usual scalar variables. A semidefinite optimization problem can be written as

minimize
$$\sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \left\langle \overline{C}_j, \overline{X}_j \right\rangle + c^f$$
subject to $l_i^c \leq \sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \left\langle \overline{A}_{ij}, \overline{X}_j \right\rangle \leq u_i^c, \quad i = 0, \dots, m-1$

$$l_j^x \leq x_j \leq u_j^x, \quad j = 0, \dots, n-1$$

$$x \in \mathcal{K}, \overline{X}_j \in \mathcal{S}_+^{r_j}, \quad j = 0, \dots, p-1$$

$$(10.9)$$

where the problem has p symmetric positive semidefinite variables $\overline{X}_j \in \mathcal{S}_+^{r_j}$ of dimension r_j with symmetric coefficient matrices $\overline{C}_j \in \mathcal{S}^{r_j}$ and $\overline{A}_{i,j} \in \mathcal{S}^{r_j}$. We use standard notation for the matrix inner product, i.e., for $U, V \in \mathbb{R}^{m \times n}$ we have

$$\langle U, V \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} U_{ij} V_{ij}.$$

With semidefinite optimization we can model a wide range of problems as demonstrated in [MOSEKApS12].

10.3.1 Duality for Semidefinite Optimization

The dual problem corresponding to the semidefinite optimization problem (10.9) is given by

maximize
$$(l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x + c^f$$
 subject to
$$c - A^T y + s_u^x - s_l^x = s_n^x,$$

$$\overline{C}_j - \sum_{i=0}^m y_i \overline{A}_{ij} = \overline{S}_j,$$
 $j = 0, \dots, p-1$ (10.10)
$$s_l^c - s_u^c = y,$$

$$s_l^c, s_u^c, s_l^x, s_u^x \ge 0,$$

$$s_n^x \in \mathcal{K}^*, \ \overline{S}_j \in \mathcal{S}_+^{r_j},$$
 $j = 0, \dots, p-1$

where $A \in \mathbb{R}^{m \times n}$, $A_{ij} = a_{ij}$, which is similar to the dual problem for conic quadratic optimization (see Section 10.2.1), except for the addition of dual constraints

$$\left(\overline{C}_j - \sum_{i=0}^m y_i \overline{A}_{ij}\right) \in \mathcal{S}_+^{r_j}.$$

Note that the dual of the dual problem is identical to the original primal problem.

10.3.2 Infeasibility for Semidefinite Optimization

In case **MOSEK** finds a problem to be infeasible it reports a certificate of the infeasibility. This works exactly as for linear problems (see Section 10.1.2).

Primal Infeasible Problems

If the problem (10.9) is infeasible, **MOSEK** will report a certificate of primal infeasibility: The dual solution reported is a certificate of infeasibility, and the primal solution is undefined.

A certificate of primal infeasibility is a feasible solution to the problem

$$\begin{array}{ll} \text{maximize} & (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x \\ \text{subject to} & \\ & A^T y + s_l^x - s_u^x + s_n^x = 0, \\ & \sum_{i=0}^{m-1} y_i \overline{A}_{ij} + \overline{S}_j = 0, \\ & -y + s_l^c - s_u^c = 0, \\ & s_l^c, s_u^c, s_l^x, s_u^x \geq 0, \\ & s_n^c \in \mathcal{K}^*, \quad \overline{S}_j \in \mathcal{S}_+^{r_j}, & j = 0, \dots, p-1 \\ \end{array}$$

such that the objective value is strictly positive.

Dual Infeasible Problems

If the problem (10.10) is infeasible, **MOSEK** will report a certificate of dual infeasibility: The primal solution reported is the certificate of infeasibility, and the dual solution is undefined.

A certificate of dual infeasibility is a feasible solution to the problem

$$\begin{array}{lll} \text{minimize} & \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \left\langle \overline{C}_j, \overline{X}_j \right\rangle \\ \text{subject to} & \hat{l}_i^c & \leq & \sum_{j=1}^n a_{ij} x_j + \sum_{j=0}^{p-1} \left\langle \overline{A}_{ij}, \overline{X}_j \right\rangle & \leq & \hat{u}_i^c, \quad i = 0, \dots, m-1 \\ & \hat{l}^x & \leq & x & \leq & \hat{u}^x, \\ & x \in \mathcal{K}, & \overline{X}_j \in \mathcal{S}_+^{r_j}, & j = 0, \dots, p-1 \end{array}$$

where

$$\hat{l}_i^c = \left\{ \begin{array}{ll} 0 & \text{if } l_i^c >; -\infty, \\ -\infty & \text{otherwise,} \end{array} \right. \quad \text{and} \quad \hat{u}_i^c := \left\{ \begin{array}{ll} 0 & \text{if } u_i^c <; \infty, \\ \infty & \text{otherwise,} \end{array} \right.$$

and

$$\hat{l}_j^x = \left\{ \begin{array}{ll} 0 & \text{if } l_j^x >; -\infty, \\ -\infty & \text{otherwise,} \end{array} \right. \quad \text{and} \quad \hat{u}_j^x := \left\{ \begin{array}{ll} 0 & \text{if } u_j^x <; \infty, \\ \infty & \text{otherwise,} \end{array} \right.$$

such that the objective value is strictly negative.

THE OPTIMIZERS FOR CONTINUOUS PROBLEMS

The most essential part of **MOSEK** is the optimizers. Each optimizer is designed to solve a particular class of problems, i.e. linear, conic, or general nonlinear problems. The purpose of the present chapter is to discuss which optimizers are available for the continuous problem classes and how the performance of an optimizer can be tuned, if needed. This chapter deals with the optimizers for *continuous problems* with no integer variables.

When the optimizer is called, it roughly performs the following steps:

- 1. Presolve: Preprocessing to reduce the size of the problem.
- 2. Dualizer: Choosing whether to solve the primal or the dual form of the problem.
- 3. Scaling: Scaling the problem for better numerical stability.
- 4. Optimize: Solve the problem using selected method.

The first three preprocessing steps are transparent to the user, but useful to know about for tuning purposes. In general, the purpose of the preprocessing steps is to make the actual optimization more efficient and robust.

Using multiple threads

The interior-point optimizers in **MOSEK** have been parallelized. This means that if you solve linear, quadratic, conic, or general convex optimization problem using the interior-point optimizer, you can take advantage of multiple CPU's.

By default **MOSEK** will automatically select the number of threads to be employed when solving the problem. However, the number of threads employed can be changed by setting the parameter <code>numThreads</code>. This should never exceed the number of cores on the computer.

The speed-up obtained when using multiple threads is highly problem and hardware dependent, and consequently, it is advisable to compare single threaded and multi threaded performance for the given problem type to determine the optimal settings.

For small problems, using multiple threads is not be worthwhile and may even be counter productive.

11.1 Presolve

Before an optimizer actually performs the optimization the problem is preprocessed using the so-called presolve. The purpose of the presolve is to

- 1. remove redundant constraints,
- 2. eliminate fixed variables,
- 3. remove linear dependencies,
- 4. substitute out (implied) free variables, and

5. reduce the size of the optimization problem in general.

After the presolved problem has been optimized the solution is automatically postsolved so that the returned solution is valid for the original problem. Hence, the presolve is completely transparent. For further details about the presolve phase, please see [AA95] and [AGMX96].

It is possible to fine-tune the behavior of the presolve or to turn it off entirely. If presolve consumes too much time or memory compared to the reduction in problem size gained it may be disabled. This is done by setting the parameter presolveUse to off.

The two most time-consuming steps of the presolve are

- the eliminator, and
- the linear dependency check.

Therefore, in some cases it is worthwhile to disable one or both of these.

Numerical issues in the presolve

During the presolve the problem is reformulated so that it hopefully solves faster. However, in rare cases the presolved problem may be harder to solve then the original problem. The presolve may also be infeasible although the original problem is not.

If it is suspected that presolved problem is much harder to solve than the original then it is suggested to first turn the eliminator off by setting the parameter *presolveEliminatorMaxNumTries* to 0. If that does not help, then trying to turn presolve off may help.

Since all computations are done in finite prescision then the presolve employs some tolerances when concluding a variable is fixed or constraint is redundant. If it happens that **MOSEK** incorrectly concludes a problem is primal or dual infeasible, then it is worthwhile to try to reduce the parameters presolveTolX and presolveTolS. However, if reducing the parameters actually helps then this should be taken as an indication that the problem is badly formulated.

Eliminator

The purpose of the eliminator is to eliminate free and implied free variables from the problem using substitution. For instance, given the constraints

$$\begin{array}{rcl} y & = & \sum_j x_j, \\ y, x & \geq & 0, \end{array}$$

y is an implied free variable that can be substituted out of the problem, if deemed worthwhile. If the eliminator consumes too much time or memory compared to the reduction in problem size gained it may be disabled. This can be done by setting the parameter presolveEliminatorMaxNumTries to 0. In rare cases the eliminator may cause that the problem becomes much hard to solve.

Linear dependency checker

The purpose of the linear dependency check is to remove linear dependencies among the linear equalities. For instance, the three linear equalities

$$\begin{array}{rcl} x_1 + x_2 + x_3 & = & 1, \\ x_1 + 0.5x_2 & = & 0.5, \\ 0.5x_2 + x_3 & = & 0.5 \end{array}$$

contain exactly one linear dependency. This implies that one of the constraints can be dropped without changing the set of feasible solutions. Removing linear dependencies is in general a good idea since it reduces the size of the problem. Moreover, the linear dependencies are likely to introduce numerical problems in the optimization phase.

It is best practise to build models without linear dependencies. If the linear dependencies are removed at the modeling stage, the linear dependency check can safely be disabled by setting the parameter <code>presolveLindepUse</code> to off.

Dualizer

All linear, conic, and convex optimization problems have an equivalent dual problem associated with them. **MOSEK** has built-in heuristics to determine if it is most efficient to solve the primal or dual problem. The form (primal or dual) solved is displayed in the **MOSEK** log. Should the internal heuristics not choose the most efficient form of the problem it may be worthwhile to set the dualizer manually by setting the parameters:

- intpntSolveForm: In case of the interior-point optimizer.
- simSolveForm: In case of the simplex optimizer.

Note that currently only linear problems may be dualized.

Scaling

Problems containing data with large and/or small coefficients, say 1.0e + 9 or 1.0e - 7, are often hard to solve. Significant digits may be truncated in calculations with finite precision, which can result in the optimizer relying on inaccurate calculations. Since computers work in finite precision, extreme coefficients should be avoided. In general, data around the same *order of magnitude* is preferred, and we will refer to a problem, satisfying this loose property, as being *well-scaled*. If the problem is not well scaled, **MOSEK** will try to scale (multiply) constraints and variables by suitable constants. **MOSEK** solves the scaled problem to improve the numerical properties.

The scaling process is transparent, i.e. the solution to the original problem is reported. It is important to be aware that the optimizer terminates when the termination criterion is met on the scaled problem, therefore significant primal or dual infeasibilities may occur after unscaling for badly scaled problems. The best solution of this issue is to reformulate the problem, making it better scaled.

By default **MOSEK** heuristically chooses a suitable scaling. The scaling for interior-point and simplex optimizers can be controlled with the parameters *intpntScaling* and *simScaling* respectively.

11.2 Linear Optimization

11.2.1 Optimizer Selection

Two different types of optimizers are available for linear problems: The default is an interior-point method, and the alternatives are simplex methods. The optimizer can be selected using the parameter optimizer.

11.2.2 The Interior-point Optimizer

The purpose of this section is to provide information about the algorithm employed in **MOSEK** interior-point optimizer.

In order to keep the discussion simple it is assumed that \mathbf{MOSEK} solves linear optimization problems of standard form

minimize
$$c^T x$$

subject to $Ax = b$, $x \ge 0$. (11.1)

This is in fact what happens inside **MOSEK**; for efficiency reasons **MOSEK** converts the problem to standard form before solving, then converts it back to the input form when reporting the solution.

Since it is not known beforehand whether problem (11.1) has an optimal solution, is primal infeasible or is dual infeasible, the optimization algorithm must deal with all three situations. This is the reason that **MOSEK** solves the so-called homogeneous model

$$\begin{array}{rcl}
Ax - b\tau & = & 0, \\
A^{T}y + s - c\tau & = & 0, \\
-c^{T}x + b^{T}y - \kappa & = & 0, \\
x, s, \tau, \kappa & \geq & 0,
\end{array}$$
(11.2)

where y and s correspond to the dual variables in (11.1), and τ and κ are two additional scalar variables. Note that the homogeneous model (11.2) always has solution since

$$(x, y, s, \tau, \kappa) = (0, 0, 0, 0, 0)$$

is a solution, although not a very interesting one.

Any solution

$$(x^*, y^*, s^*, \tau^*, \kappa^*)$$

to the homogeneous model (11.2) satisfies

$$x_j^* s_j^* = 0$$
 and $\tau^* \kappa^* = 0$.

Moreover, there is always a solution that has the property

$$\tau^* + \kappa^* > 0.$$

First, assume that $\tau^* > 0$. It follows that

$$\begin{array}{cccc} A\frac{x^*}{\tau^*} & = & b, \\ A^T\frac{y^*}{\tau^*} + \frac{s^*}{\tau^*} & = & c, \\ -c^T\frac{x^*}{\tau^*} + b^T\frac{y}{\tau^*} & = & 0, \\ x^*, s^*, \tau^*, \kappa^* & \geq & 0. \end{array}$$

This shows that $\frac{x^*}{\tau^*}$ is a primal optimal solution and $(\frac{y^*}{\tau^*}, \frac{s^*}{\tau^*})$ is a dual optimal solution; this is reported as the optimal interior-point solution since

$$(x, y, s) = \left\{ \frac{x^*}{\tau^*}, \frac{y^*}{\tau^*}, \frac{s^*}{\tau^*} \right\}$$

is a primal-dual optimal solution.

On other hand, if $\kappa^* > 0$ then

$$\begin{array}{rcl} Ax^* & = & 0, \\ A^Ty^* + s^* & = & 0, \\ -c^Tx^* + b^Ty^* & = & \kappa^*, \\ x^*, s^*, \tau^*, \kappa^* & \geq & 0. \end{array}$$

This implies that at least one of

$$-c^T x^* > 0 \tag{11.3}$$

or

$$b^T y^* > 0 \tag{11.4}$$

is satisfied. If (11.3) is satisfied then x^* is a certificate of dual infeasibility, whereas if (11.4) is satisfied then y^* is a certificate of dual infeasibility.

In summary, by computing an appropriate solution to the homogeneous model, all information required for a solution to the original problem is obtained. A solution to the homogeneous model can be computed using a primal-dual interior-point algorithm [And09].

Interior-point Termination Criterion

For efficiency reasons it is not practical to solve the homogeneous model exactly. Hence, an exact optimal solution or an exact infeasibility certificate cannot be computed and a reasonable termination criterion has to be employed.

In every iteration, k, of the interior-point algorithm a trial solution

$$(x^k, y^k, s^k, \tau^k, \kappa^k)$$

to homogeneous model is generated where

$$x^k, s^k, \tau^k, \kappa^k > 0.$$

Whenever the trial solution satisfies the criterion

$$\left\| A \frac{x^{k}}{\tau^{k}} - b \right\|_{\infty} \leq \epsilon_{p} (1 + \|b\|_{\infty}),
\left\| A^{T} \frac{y^{k}}{\tau^{k}} + \frac{s^{k}}{\tau^{k}} - c \right\|_{\infty} \leq \epsilon_{d} (1 + \|c\|_{\infty}), \text{ and}
\min \left(\frac{(x^{k})^{T} s^{k}}{(\tau^{k})^{2}}, \left| \frac{c^{T} x^{k}}{\tau^{k}} - \frac{b^{T} y^{k}}{\tau^{k}} \right| \right) \leq \epsilon_{g} \max \left(1, \frac{\min(\left| c^{T} x^{k} \right|, \left| b^{T} y^{k} \right|)}{\tau^{k}} \right),$$
(11.5)

the interior-point optimizer is terminated and

$$\frac{(x^k, y^k, s^k)}{\tau^k}$$

is reported as the primal-dual optimal solution. The interpretation of (11.5) is that the optimizer is terminated if

- $\frac{x^k}{\tau^k}$ is approximately primal feasible,
- $\bullet \ \left\{ \frac{y^k}{\tau^k}, \frac{s^k}{\tau^k} \right\}$ is approximately dual feasible, and
- the duality gap is almost zero.

On the other hand, if the trial solution satisfies

$$-\epsilon_i c^T x^k > \frac{\|c\|_{\infty}}{\max\left(1, \|b\|_{\infty}\right)} \|Ax^k\|_{\infty}$$

then the problem is declared dual infeasible and x^k is reported as a certificate of dual infeasibility. The motivation for this stopping criterion is as follows: First assume that $\|Ax^k\|_{\infty} = 0$; then x^k is an exact certificate of dual infeasibility. Next assume that this is not the case, i.e.

$$||Ax^k||_{\infty} > 0,$$

and define

$$\bar{x} := \epsilon_i \frac{\max\left(1, \|b\|_{\infty}\right)}{\|Ax^k\|_{\infty} \|c\|_{\infty}} x^k.$$

It is easy to verify that

$$||A\bar{x}||_{\infty} = \epsilon_i \frac{\max(1, ||b||_{\infty})}{||c||_{\infty}} \text{ and } -c^T \bar{x} > 1,$$

which shows \bar{x} is an approximate certificate of dual infeasibility where ε_i controls the quality of the approximation. A smaller value means a better approximation.

Finally, if

$$\epsilon_i b^T y^k > \frac{\|b\|_{\infty}}{\max\left(1, \|c\|_{\infty}\right)} \left\|A^T y^k + s^k\right\|_{\infty}$$

then y^k is reported as a certificate of primal infeasibility.

It is possible to adjust the tolerances ε_p , ε_d , ε_g and ε_i using parameters; see Table 11.1 for details.

Table 11.1: Parameters employed in termination criterion

ToleranceParameter	name
$arepsilon_p$	intpntTolPfeas
$arepsilon_d$	intpntTolDfeas
ε_g	intpntTolRelGap
$arepsilon_i$	intpntTolInfeas

The default values of the termination tolerances are chosen such that for a majority of problems appearing in practice it is not possible to achieve much better accuracy. Therefore, tightening the tolerances usually is not worthwhile. However, an inspection of (11.5) reveals that quality of the solution is dependent on $||b||_{\infty}$ and $||c||_{\infty}$; the smaller the norms are, the better the solution accuracy.

The interior-point method as implemented by **MOSEK** will converge toward optimality and primal and dual feasibility at the same rate [And09]. This means that if the optimizer is stopped prematurely then it is very unlikely that either the primal or dual solution is feasible. Another consequence is that in most cases all the tolerances, ε_p , ε_d and ε_g , have to be relaxed together to achieve an effect.

In some cases the interior-point method terminates having found a solution not too far from meeting the optimality condition (11.5). A solution is defined as near optimal if scaling ε_p , ε_d and ε_g by any number $\varepsilon_n \in [1.0, +\infty]$ conditions (11.5) are satisfied.

A near optimal solution is therefore of lower quality but still potentially valuable. If for instance the solver stalls, i.e. it can make no more significant progress towards the optimal solution, a near optimal solution could be available and be good enough for the user.

The basis identification discussed in Section Basis Identification requires an optimal solution to work well; hence basis identification should be turned off if the termination criterion is relaxed.

To conclude the discussion in this section, relaxing the termination criterion is usually not worthwhile.

Basis Identification

An interior-point optimizer does not return an optimal basic solution unless the problem has a unique primal and dual optimal solution. Therefore, the interior-point optimizer has an optimal post-processing step that computes an optimal basic solution starting from the optimal interior-point solution. More information about the basis identification procedure may be found in [AY96]. In the following we provide an overall idea of the procedure.

There are some cases in which a basic solution could be more valuable:

- a basic solution is often more accurate than an interior-point solution,
- a basic solution can be used to warm-start the simplex algorithm in case of reoptimization,
- a basic solution is in general more sparse, i.e. more variables are fixed to zero. This is particularly appealing when solving continuous relaxation of mixed integer problems, as well as in all applications in which sparser solutions are preferred.

To illustrate how the basis identification routine works, we use the following trivial example:

$$\begin{array}{lll} \mbox{minimize} & x+y \\ \mbox{subject to} & x+y & = & 1, \\ & x,y \geq 0. \end{array}$$

It is easy to see that all feasible solutions are also optimal. In particular, there are two basic solutions namely

$$\begin{array}{rcl} (x_1^*,y_1^*) & = & (1,0), \\ (x_2^*,y_2^*) & = & (0,1). \end{array}$$

The interior point algorithm will actually converge to the center of the optimal set, i.e. to $(x^*, y^*) = (1/2, 1/2)$ (to see this in **MOSEK** deactivate *Presolve*).

In practice, when the algorithm gets close to the optimal solution, it is possible to construct in polynomial time an initial basis for the simplex algorithm from the current interior point solution. This basis is used to warm-start the simplex algorithm that will provide the optimal basic solution.

In most cases the constructed basis is optimal, or very few iterations are required by the simplex algorithm to make it optimal and hence the final *clean* phase be short. However, in some cases for nasty problems e.g. ill-conditioned problems the additional simplex clean up phase may take of lot a time.

By default **MOSEK** performs a basis identification. However, if a basic solution is not needed, the basis identification procedure can be turned off. The parameters

- intpntBasis,
- biIgnoreMaxIter, and
- biIqnoreNumError

control when basis identification is performed.

The type of simplex algorithm to be used can be tuned by the biCleanOptimizer parameter i.e. primal or dual simplex, and the maximum number of iterations can be set by the biMaxIterations.

Finally, it should be mentioned that there is no guarantee on which basic solution will be returned.

The Interior-point Log

Below is a typical log output from the interior-point optimizer presented:

```
Optimizer - threads
                                   : 1
Optimizer

```

The first line displays the number of threads used by the optimizer and second line tells that the optimizer chose to solve the dual problem rather than the primal problem. The next line displays the problem dimensions as seen by the optimizer, and the Factor... lines show various statistics. This is followed by the iteration log.

Using the same notation as in Section 11.2.2 the columns of the iteration log have the following meaning:

- ITE: Iteration index.
- PFEAS: $||Ax^k b\tau^k||_{\infty}$. The numbers in this column should converge monotonically towards to zero but may stall at low level due to rounding errors.
- DFEAS: $\|A^Ty^k + s^k c\tau^k\|_{\infty}$. The numbers in this column should converge monotonically toward to zero but may stall at low level due to rounding errors.

- GFEAS: $|-c^Tx^k+b^Ty^k-\kappa^k|$. The numbers in this column should converge monotonically toward to zero but may stall at low level due to rounding errors.
- PRSTATUS: This number converges to 1 if the problem has an optimal solution whereas it converges to -1 if that is not the case.
- POBJ: $c^T x^k / \tau^k$. An estimate for the primal objective value.
- DOBJ: $b^T y^k / \tau^k$. An estimate for the dual objective value.
- MU: $\frac{(x^k)^T s^k + \tau^k \kappa^k}{n+1}$. The numbers in this column should always converge monotonically to zero.
- TIME: Time spend since the optimization started.

11.2.3 The simplex Based Optimizer

An alternative to the interior-point optimizer is the simplex optimizer.

The simplex optimizer uses a different method that allows exploiting an initial guess for the optimal solution to reduce the solution time. Depending on the problem it may be faster or slower to use an initial guess; see section 11.2.4 for a discussion.

MOSEK provides both a primal and a dual variant of the simplex optimizer — we will return to this later

Simplex Termination Criterion

The simplex optimizer terminates when it finds an optimal basic solution or an infeasibility certificate. A basic solution is optimal when it is primal and dual feasible; see Section 10.1 and 10.1.1 for a definition of the primal and dual problem. Due to the fact that computations are performed in finite precision **MOSEK** allows violation of primal and dual feasibility within certain tolerances. The user can control the allowed primal and dual tolerances with the parameters basisTolX and basisTolS.

Starting From an Existing Solution

When using the simplex optimizer it may be possible to reuse an existing solution and thereby reduce the solution time significantly. When a simplex optimizer starts from an existing solution it is said to perform a *warm-start*. If the user is solving a sequence of optimization problems by solving the problem, making modifications, and solving again, **MOSEK** will warm-start automatically.

Setting the parameter optimizer to freeSimplex instructs MOSEK to select automatically between the primal and the dual simplex optimizers. Hence, MOSEK tries to choose the best optimizer for the given problem and the available solution.

By default **MOSEK** uses presolve when performing a warm-start. If the optimizer only needs very few iterations to find the optimal solution it may be better to turn off the presolve.

Numerical Difficulties in the Simplex Optimizers

Though MOSEK is designed to minimize numerical instability, completely avoiding it is impossible when working in finite precision. MOSEK counts a "numerical unexpected behavior" event inside the optimizer as a *set-back*. The user can define how many set-backs the optimizer accepts; if that number is exceeded, the optimization will be aborted. Set-backs are implemented to avoid long sequences where the optimizer tries to recover from an unstable situation.

Set-backs are, for example, repeated singularities when factorizing the basis matrix, repeated loss of feasibility, degeneracy problems (no progress in objective) and other events indicating numerical difficulties. If the simplex optimizer encounters a lot of set-backs the problem is usually badly scaled; in such a situation try to reformulate into a better scaled problem. Then, if a lot of set-backs still occur, trying one or more of the following suggestions may be worthwhile:

- Raise tolerances for allowed primal or dual feasibility: Hence, increase the value of
 - basisTolX, and
 - basisTolS.
- Raise or lower pivot tolerance: Change the <code>simplexAbsTolPiv</code> parameter.
- Switch optimizer: Try another optimizer.
- Switch off crash: Set both simPrimalCrash and simDualCrash to 0.
- Experiment with other pricing strategies: Try different values for the parameters
 - simPrimalSelection and
 - simDualSelection.
- If you are using warm-starts, in rare cases switching off this feature may improve stability. This is controlled by the <code>simHotstart</code> parameter.
- Increase maximum set backs allowed controlled by simMaxNumSetbacks.
- If the problem repeatedly becomes infeasible try switching off the special degeneracy handling. See the parameter <code>simDegen</code> for details.

11.2.4 The Interior-point or the Simplex Optimizer?

Given a linear optimization problem, which optimizer is the best: The primal simplex, the dual simplex or the interior-point optimizer?

It is impossible to provide a general answer to this question. However, the interior-point optimizer behaves more predictably: it tends to use between 20 and 100 iterations, almost independently of problem size, but cannot perform warm-start, while simplex can take advantage of an initial solution, but is less predictable for cold-start. The interior-point optimizer is used by default.

11.2.5 The Primal or the Dual Simplex Variant?

MOSEK provides both a primal and a dual simplex optimizer. Predicting which simplex optimizer is faster is impossible, however, in recent years the dual optimizer has seen several algorithmic and computational improvements, which, in our experience, makes it faster on average than the primal simplex optimizer. Still, it depends much on the problem structure and size.

Setting the *optimizer* parameter to freeSimplex instructs MOSEK to choose which simplex optimizer to use automatically.

To summarize, if you want to know which optimizer is faster for a given problem type, you should try all the optimizers.

11.3 Conic Optimization

11.3.1 The Interior-point Optimizer

For conic optimization problems only an interior-point type optimizer is available. The interior-point optimizer is an implementation of the so-called homogeneous and self-dual algorithm. For a detailed description of the algorithm, please see [ART03].

Interior-point Termination Criteria

The parameters controlling when the conic interior-point optimizer terminates are shown in Table 11.2.

Controls when the problem is declared infeasible

Controls when the complementarity is reduced enough

Parameter name Purpose

intpntCoTolPfeas Controls primal feasibility

intpntCoTolDfeas Controls dual feasibility

Table 11.2: Parameters employed in termination criterion.

11.4 Using Multiple Threads in an Optimizer

Controls relative gap

If multiple cores are available then it is possible for **MOSEK** to take advantage of them to speed up the computation. However, please note the speedup achieved is going to be dependent on the problem characteristics e.g. the size of problem. Typically for smallish problems no speedup is obtained by exploiting multiple cores. In fact forcing **MOSEK** to use one core can increase speed because parallel overhead is avoided.

11.4.1 Thread Safety

intpntCoTolRelGap

intpntTolInfeas

intpntCoTolMuRed

The MOSEK API is thread-safe provided that a task is only modified or accessed from one thread at any given time. Also accessing two or more separate tasks from threads at the same time is safe. Sharing an environment between threads is safe.

11.4.2 Determinism

The optimizers are run-to-run deterministic which means if a problem is solved twice on the same computer using the same parameter setting and exactly the same input then exactly the same results is obtained. One qualification is that no time limits must be imposed because the time taken to perform an operation on a computer is dependent on many factors such as the current workload.

11.4.3 The Parallelized Interior-point Optimizer

By default the interior-point optimizer exploits multiple cores using multithreading. Hence, big tasks such as large dense matrix multiplication may be divided into several independent smaller tasks that can be computed independently. However, there is a computational overhead associated with exploiting multiple threads e.g. cost of the additional coordination etc. Therefore, it may be advantageous to turn off the multibreading for smallish problem using the parameter <code>intpntMultiThread</code>.

Moreover, when the interior-point optimizer is allowed to exploit multiple threads, then the parameter *numThreads* controls the maximum number of threads (and therefore the number of cores) that **MOSEK** will employ.

THE OPTIMIZER FOR MIXED-INTEGER PROBLEMS

A problem is a mixed-integer optimization problem when one or more of the variables are constrained to be integer valued. **MOSEK** can solve mixed-integer

- linear.
- quadratic and quadratically constrained, and
- conic qudratic

problems.

Readers unfamiliar with integer optimization are recommended to consult some relevant literature, e.g. the book [Wol98] by Wolsey.

12.1 Some Concepts and Facts Related to Mixed-integer Optimization

It is important to understand that in a worst-case scenario, the time required to solve integer optimization problems grows exponentially with the size of the problem. For instance, assume that a problem contains n binary variables, then the time required to solve the problem in the worst case may be proportional to 2^n . The value of 2^n is huge even for moderate values of n.

In practice this implies that the focus should be on computing a near optimal solution quickly rather than on locating an optimal solution. Even if the problem is only solved approximately, it is important to know how far the approximate solution is from an optimal one. In order to say something about the quality of an approximate solution the concept of *relaxation* is important.

The mixed-integer optimization problem

$$z^* = \underset{\text{subject to}}{\text{minimize}} c^T x$$

$$x \ge 0$$

$$x_j \in \mathbb{Z}, \quad \forall j \in \mathcal{J},$$

$$(12.1)$$

has the continuous relaxation

$$\underline{z} = \underset{\text{subject to}}{\text{minimize}} \quad c^T x \\ \text{subject to} \quad Ax = b, \\ x \ge 0$$
 (12.2)

The continuos relaxation is identical to the mixed-integer problem with the restriction that some variables must be integers removed.

There are two important observations about the continuous relaxation. First, the continuous relaxation is usually much faster to optimize than the mixed-integer problem. Secondly if \hat{x} is any feasible solution to (12.1) and

$$\bar{z} := c^T \hat{x}$$

then

$$\underline{z} \le z^* \le \bar{z}$$
.

This is an important observation since if it is only possible to find a near optimal solution within a reasonable time frame then the quality of the solution can nevertheless be evaluated. The value \underline{z} is a lower bound on the optimal objective value. This implies that the obtained solution is no further away from the optimum than $\overline{z} - \underline{z}$ in terms of the objective value.

Whenever a mixed-integer problem is solved **MOSEK** reports this lower bound so that the quality of the reported solution can be evaluated.

12.2 The Mixed-integer Optimizer

The mixed-integer optimizer can handle problems with linear, quadratic objective and constraints and conic constraints. However, a problem can not contain both quadratic objective or constraints and conic constraints

The mixed-integer optimizer is specialized for solving linear and conic optimization problems. It can also solve pure quadratic and quadratically constrained problems; these problems are automatically converted to conic problems before being solved.

The mixed-integer optimizer is run-to-run deterministic. This means that if a problem is solved twice on the same computer with identical options then the obtained solution will be bit-for-bit identical for the two runs. However, if a time limit is set then this may not be case since the time taken to solve a problem is not deterministic. The mixed-integer optimizer is parallelized i.e. it can exploit multiple cores during the optimization.

The solution process can be split into these phases:

- 1. **Presolve:** In this phase the optimizer tries to reduce the size of the problem and improve the formulation using preprocessing techniques. The presolve stage can be turned off using the *presolveUse* parameter
- 2. Cut generation: Valid inequalities (cuts) are added to improve the lower bound
- 3. **Heuristic:** Using heuristics the optimizer tries to guess a good feasible solution. Heuristics can be controlled by the parameter *mioHeuristicLevel*
- 4. Search: The optimal solution is located by branching on integer variables

12.3 Termination Criterion

In general, it is time consuming to find an exact feasible and optimal solution to an integer optimization problem, though in many practical cases it may be possible to find a sufficiently good solution. Therefore, the mixed-integer optimizer employs a relaxed feasibility and optimality criterion to determine when a satisfactory solution is located.

A candidate solution that is feasible for the continuous relaxation is said to be an integer feasible solution if the criterion

$$\min(x_i - |x_i|, \lceil x_i \rceil - x_i) \le \delta_1 \quad \forall j \in \mathcal{J}$$

is satisfied, meaning that x_j is at most δ_1 from the nearest integer.

Whenever the integer optimizer locates an integer feasible solution it will check if the criterion

$$\bar{z} - z < \max(\delta_2, \delta_3 \max(10^{-10}, |\bar{z}|))$$

is satisfied. If this is the case, the integer optimizer terminates and reports the integer feasible solution as an optimal solution. Please note that \underline{z} is a valid lower bound determined by the integer optimizer during the solution process, i.e.

$$\underline{z} \leq z^*$$
.

The lower bound z normally increases during the solution process.

12.3.1 Relaxed Termination

If an optimal solution cannot be located within a reasonable time, it may be advantageous to employ a relaxed termination criterion after some time. Whenever the integer optimizer locates an integer feasible solution and has spent at least the number of seconds defined by the <code>mioDisableTermTime</code> parameter on solving the problem, it will check whether the criterion

$$\bar{z} - \underline{z} \le \max(\delta_4, \delta_5 \max(10^{-10}, |\bar{z}|))$$

is satisfied. If it is satisfied, the optimizer will report that the candidate solution is **near optimal** and then terminate. Please note that since this criterion depends on timing, the optimizer will not be run to run deterministic.

12.4 Parameters Affecting the Termination of the Integer Optimizer.

All δ tolerances can be adjusted using suitable parameters — see Table 12.1.

Table 12.1: Tolerances for the mixed-integer optimizer.

Tolerance	Parameter name
δ_1	${\it mioTolAbsRelaxInt}$
δ_2	mioTolAbsGap
δ_3	mioTolRelGap
δ_4	mioNearTolAbsGap
δ_5	mioNearTolRelGap

In Table 12.2 some other parameters affecting the integer optimizer termination criterion are shown. Please note that if the effect of a parameter is delayed, the associated termination criterion is applied only after some time, specified by the <code>mioDisableTermTime</code> parameter.

Table 12.2: Other parameters affecting the integer optimizer termination criterion.

Parameter name	Delayed	Explanation
${\it mioMaxNumBranches}$	Yes	Maximum number of branches allowed.
${\it mioMaxNumRelaxs}$	Yes	Maximum number of relaxations allowed.
${\it mioMaxNumSolutions}$	Yes	Maximum number of feasible integer solutions allowed.

12.5 How to Speed Up the Solution Process

As mentioned previously, in many cases it is not possible to find an optimal solution to an integer optimization problem in a reasonable amount of time. Some suggestions to reduce the solution time are:

• Relax the termination criterion: In case the run time is not acceptable, the first thing to do is to relax the termination criterion — see Section 12.3 for details.

- Specify a good initial solution: In many cases a good feasible solution is either known or easily computed using problem specific knowledge. If a good feasible solution is known, it is usually worthwhile to use this as a starting point for the integer optimizer.
- Improve the formulation: A mixed-integer optimization problem may be impossible to solve in one form and quite easy in another form. However, it is beyond the scope of this manual to discuss good formulations for mixed-integer problems. For discussions on this topic see for example [Wol98].

12.6 Understanding Solution Quality

To determine the quality of the solution one should check the following:

- The solution status key returned by MOSEK
- The *optimality gap*: A measure of how much the located solution can deviate from the optimal solution to the problem
- Feasibility. How much the solution violates the constraints of the problem

The *optimality gap* is a measure for how close the solution is to the optimal solution. The optimality gap is given by

 $\epsilon = |(\text{objective value of feasible solution}) - (\text{objective bound})|.$

The objective value of the solution is guarantied to be within ϵ of the optimal solution.

The optimality gap can be retrieved through the solution item mioObjAbsGap. Often it is more meaningful to look at the optimality gap normalized with the magnitude of the solution. The relative optimality gap is available in mioObjRelGap.

THIRTEEN

FUSION API REFERENCE

13.1 Class list

Most commonly used

- Constraint: Abstract base class for Constraint objects.
- Domain: Base class for variable and constraint domains.
- Expr: Represents a linear expression and provides linear operators.
- Expression: Abstract base class for all objects which can be used as linear expressions.
- Matrix: Base class for all matrix objects.
- Model: The object containing all data related to a single optimization model.
- NDSparseArray: Representation of a sparse n-dimensional array
- \bullet Set: Base class shape specification objects.
- SymmetricLinearDomain: Represent a linear domain with symmetry.
- Var: Provides basic operations on variable objects.
- Variable: Abstract base class for Variable objects.

For advanced users

- BaseSet: Base class for 1-dimensional sets.
- BaseVariable: Abstract base class for Variable objects with default implementations.
- BoundInterfaceConstraint: Interface to either the upper bound or the lower bound of a ranged constraint.
- BoundInterfaceVariable: Interface to either the upper bound or the lower bound of a ranged variable.
- \bullet CompoundConstraint: Stacking of contraints.
- CompoundVariable: A stack of several other variables.
- ConicConstraint: Represent a conic constraint.
- Conic Variable: Represent a conic variable.
- FlatExpr: A simple sparse representation of a linear expression.
- \bullet Lin PSDDomain: Represent a linear PSD domain.
- LinearConstraint: An object representing a block of linear constraints of the same type.
- LinearDomain: Represent a domain defined by linear constraints

- LinearPSDConstraint: Represents a semidefinite conic constraint.
- LinearPSDVariable: This class represents a positive semidefinite variable.
- LinearVariable: An object representing a block of linear variables of the same type.
- ModelConstraint: Represent a block of constraints.
- ModelVariable: Represent a block of variables.
- PSDConstraint: Represents a semidefinite conic constraint.
- PSDDomain: Represent the domain od PSD matrices.
- *PSDVariable*: This class represents a positive semidefinite variable.
- PickVariable: Represents an set of variable entries
- ProductSet: None
- QConeDomain: A domain representing the Lorentz cone.
- RangeDomain: The range domain represents a ranged subset of the euclidian space.
- RangedConstraint: Defines a ranged constraint.
- RangedVariable: Defines a ranged variable.
- SliceConstraint: An alias for a subset of constraints from a single ModelConstraint.
- SliceVariable: An alias for a subset of variables from a single model variable.
- SymLinearVariable: An object representing a block of linear variables of the same type.
- SymRangedVariable: Defines a symmetric ranged variable.
- SymmetricExpr: An object representing a symmetric expression.
- SymmetricRangeDomain: Represent a ranged domain with symmetry.
- Symmetric Variable: An object representing a symmetric variable.

13.1.1 Class BaseSet

```
mosek.fusion.BaseSet
```

Base class for 1-dimensional sets.

Members

```
BaseSet.dim - Return the size of the given dimension.
```

Set.compare - Compare two sets and return true if they have the same shape and size.

Set.getSize - Total number of elements in the set.

Set.getname - Return a string representing the index.

Set. idxtokey - Convert a linear index to a N-dimensional key.

Set.realnd - Number of dimensions of more than 1 element, or 1 if the number of significant dimensions is 0.

Set.slice - Create a set object representing a slice of this set.

Set. stride - Return the stride size in the given dimension.

Set. toString - Return a string representation of the set.

Implements

Set

ret = BaseSet.dim(i)

Return the size of the given dimension.

Parameters

```
•i (int32) - Dimension index.
```

Return

•ret (int32) - The size of the requested dimension.

13.1.2 Class BaseVariable

```
mosek.fusion.BaseVariable
```

An abstract variable object. This is class provides various default implementations of methods in *Variable*.

Members

BaseVariable.antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr - Create an expression corresponding to the variable object.

BaseVariable.diag - Return the diagonal of a square variable matrix.

BaseVariable.dual - Get the dual solution value of the variable.

BaseVariable.getModel - Return the model to which the variable belongs

BaseVariable.getShape - Return the model to which the variable belongs

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable. level - Get the primal solution value of the variable.

BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any

BaseVariable.makeInteger - Apply integrality constraints on the variable

BaseVariable.pick - Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel - Input solution values for this variable

BaseVariable.shape - Return the shape of the variable.

BaseVariable.size - Get the number of elements in the variable.

BaseVariable.slice — Create a slice variable by picking a range of indexes for each variable dimension

BaseVariable. toString - Create a string-representation of the variable.

BaseVariable.transpose - Transpose a vector or matrix variable

Implemented by

```
{\it Compound Variable}\,,\,\,{\it Slice Variable}\,,\,\,{\it Model Variable}\,,\,\,{\it Pick Variable}\,
```

```
ret = BaseVariable.antidiag()
```

ret = BaseVariable.antidiag(index)

Return the antidiagonal of a square variable matrix.

Parameters

•index (int32) – Index of the anti-diagonal

Return

•ret (Variable)

ret = BaseVariable.asExpr()

Create an expression corresponding to the variable object.

Return

```
•ret (Expression)
```

```
ret = BaseVariable.diag()
```

ret = BaseVariable.diag(index)

Return the diagonal of a square variable matrix.

13.1. Class list 133

```
Parameters
         \bulletindex (int32) – Index of the anti-diagonal
Return
         •ret (Variable)
ret = BaseVariable.dual()
     Get the dual solution value of the variable.
Return
         •ret (double[])
ret = BaseVariable.getModel()
     Return the model to which the variable belongs
Return
         •ret (Model)
ret = BaseVariable.getShape()
     Return the model to which the variable belongs
Return
         •ret (Set)
ret = BaseVariable.index(index)
ret = BaseVariable.index(index2)
ret = BaseVariable.index(i0, i1)
ret = BaseVariable.index(i0, i1, i2)
     Return a variable slice of size 1 corresponding to a single element in the variable object..
Parameters
         •index (int32)
         •index2 (int32[])
         •i0 (int32) - Index in the first dimension of the element requested.
         •i1 (int32) - Index in the second dimension of the element requested.
         •i2 (int32) – Index in the second dimension of the element requested.
Return
         •ret (Variable)
ret = BaseVariable.level()
     Get the primal solution value of the variable.
Return
         •ret (double[])
ret = BaseVariable.makeContinuous()
     Drop integrality constraints on the variable, if any
Return
         •ret (void)
ret = BaseVariable.makeInteger()
     Apply integrality constraints on the variable
Return
         •ret (void)
ret = BaseVariable.pick(idxs)
ret = BaseVariable.pick(midxs)
ret = BaseVariable.pick(i0, i1)
ret = BaseVariable.pick(i0, i1, i2)
     Create a slice variable by picking a list of indexes from this variable.
```

Parameters

```
•idxs (int32[]) - Indexes of the elements requested.
         •midxs (int32[][]) - Matrix of indexes of the elements requested.
         •i0 (int32[])
         •i1 (int32[]) - Index along the first dimension.
         •i2 (int32[]) - Index along the second dimension.
Return
         ●ret (Variable)
ret = BaseVariable.setLevel(v)
     Input solution values for this variable
Parameters
         •v (double[]) - An array of values to be assigned to the variable.
Return
         •ret (void)
ret = BaseVariable.shape()
     Return the shape of the variable.
Return
         •ret (Set)
ret = BaseVariable.size()
     Get the number of elements in the variable.
Return
         •ret (int64)
ret = BaseVariable.slice(first, last)
ret = BaseVariable.slice(first2, last2)
     Create a slice variable by picking a range of indexes for each variable dimension
Parameters
         •first (int32) - The index of the first element(s) of the slice.
         •last (int32) - The index of the first element after the end of the slice.
         •first2 (int32[]) - The index of the first element(s) of the slice.
         •last2 (int32[])
Return
         ●ret (Variable)
ret = BaseVariable.toString()
     Create a string-representation of the variable.
Return
         •ret (string)
ret = BaseVariable.transpose()
     Transpose a vector or matrix variable
Return
         ●ret (Variable)
```

13.1.3 Class BoundInterfaceConstraint

${\tt mosek.fusion.BoundInterfaceConstraint}$

Interface to either the upper bound or the lower bound of a ranged constraint.

13.1. Class list 135

This class is never explicitly instantiated; is is created by a *RangedConstraint* to allow accessing a bound value and the dual variable value corresponding to the relevant bound as a separate object. The constraint

$$b_l \le a^T x \le b_u$$

has two bounds and two dual variables; these are not immediately available through the <code>RangedConstraint</code> object, but can be accessed through a <code>BoundInterfaceConstraint</code>.

Members

Constraint.add – Add an expression to the constraint expression.

 ${\it Constraint.dual}$

Constraint.get_model - Get the original model object.

Constraint.get_nd - Get the number of dimensions of the constraint.

Constraint. index - Get a single element from a one-dimensional constraint.

Constraint. level - Get the primal solution value of the variable.

Constraint.shape

Constraint. toString - Create a human readable representation of the constraint.

SliceConstraint.size - Get the total number of elements in the constraint.

SliceConstraint.slice

Implements

SliceConstraint

13.1.4 Class BoundInterfaceVariable

mosek.fusion.BoundInterfaceVariable

Interface to either the upper bound or the lower bound of a ranged variable.

This class is never explicitly instantiated; is is created by a <code>RangedVariable</code> to allow accessing a bound value and the dual variable value corresponding to the relevant bound as a separate object. The variable

$$b_l \le x \le b_u$$

has two bounds and two dual variables; these are not immediately available through the ${\it RangedVariable}$ object, but can be accessed through a ${\it BoundInterfaceVariable}$.

Members

BaseVariable. antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr - Create an expression corresponding to the variable object.

BaseVariable.diag - Return the diagonal of a square variable matrix.

BaseVariable.dual - Get the dual solution value of the variable.

BaseVariable.getModel - Return the model to which the variable belongs

 ${\it BaseVariable.getShape}$ – Return the model to which the variable belongs

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable. level - Get the primal solution value of the variable.

BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any

BaseVariable.makeInteger - Apply integrality constraints on the variable

```
BaseVariable.pick - Create a slice variable by picking a list of indexes from this variable.
```

BaseVariable.setLevel - Input solution values for this variable

BaseVariable. shape - Return the shape of the variable.

BaseVariable.size - Get the number of elements in the variable.

BaseVariable. toString - Create a string-representation of the variable.

BaseVariable.transpose - Transpose a vector or matrix variable

SliceVariable.slice — Create a slice variable by picking a range of indexes for each variable dimension

Implements

SliceVariable

13.1.5 Class CompoundConstraint

```
mosek.fusion.CompoundConstraint
```

Stacking of constraints.

A CompoundConstraint represents a stack or other variable objects and can be used as a 1-dimensional variable. The class is never explicitly instantiated, but is created using Constraint.stack.

As this class is derived from <code>Variable</code>, it may be used as a normal variable when creating expressions.

Members

```
CompoundConstraint.slice - Unimplemented method!.
```

Constraint.add – Add an expression to the constraint expression.

Constraint.dual

Constraint.get_model - Get the original model object.

 ${\it Constraint.get_nd}$ — Get the number of dimensions of the constraint.

Constraint.index - Get a single element from a one-dimensional constraint.

Constraint. level - Get the primal solution value of the variable.

Constraint.shape

Constraint.size - Get the total number of elements in the constraint.

Constraint. to String - Create a human readable representation of the constraint.

${\tt Implements}$

Constraint

```
ret = CompoundConstraint.slice(first, last)
```

ret = CompoundConstraint.slice(firsta, lasta)

Unimplemented method!.

Parameters

- •first (int32) Index of the first element in the slice.
- •last (int32) Index if the last element in the slice.
- •firsta (int32[]) Array of start elements in the slice.
- •lasta (int32[]) Array of end element in the slice.

Return

•ret (Constraint)

13.1. Class list 137

13.1.6 Class CompoundVariable

```
mosek.fusion.CompoundVariable
     A stack of several other variables.
     A compound variable represents a stack og other variable objects and can be used as a 1-dimensional
     variable. The class is never explicitly instantiated, but is created using Var. stack.
     Members
     Base Variable. antidiag - Return the antidiagonal of a square variable matrix.
     Base Variable. diag - Return the diagonal of a square variable matrix.
     BaseVariable.dual - Get the dual solution value of the variable.
     BaseVariable.getModel - Return the model to which the variable belongs
     BaseVariable.getShape - Return the model to which the variable belongs
     BaseVariable. index - Return a variable slice of size 1 corresponding to a single element in the
     variable object..
     BaseVariable. level - Get the primal solution value of the variable.
     BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any
     BaseVariable.makeInteger - Apply integrality constraints on the variable
     BaseVariable.pick - Create a slice variable by picking a list of indexes from this variable.
     BaseVariable.setLevel - Input solution values for this variable
     BaseVariable. shape - Return the shape of the variable.
     BaseVariable.size - Get the number of elements in the variable.
     BaseVariable. toString - Create a string-representation of the variable.
     BaseVariable.transpose - Transpose a vector or matrix variable
     CompoundVariable.asExpr - Create an expression corresponding to the variable object.
     CompoundVariable.slice - Create a slice variable by picking a range of indexes for each variable
     dimension
Implements
     BaseVariable
ret = CompoundVariable.asExpr()
     Create an expression corresponding to the variable object.
Return
         •ret (Expression)
ret = CompoundVariable.slice(first, last)
ret = CompoundVariable.slice(first2, last2)
     Create a slice variable by picking a range of indexes for each variable dimension
Parameters
         •first (int32) – The index of the first element(s) of the slice.
         •last (int32) - The index of the first element after the end of the slice.
         •first2 (int32[]) - The index of the first element(s) of the slice.
```

Return

•ret (Variable)

•last2 (int32[])

13.1.7 Class ConicConstraint

mosek.fusion.ConicConstraint

This class represents a conic constraint of the form

$$Ax - b \in \mathcal{K}$$

where K is either a quadratic cone or a rotated quadratic cone. Then class is never explicitly instantiated, but is created using Model.constraint by specifying a conic domain.

Note that a conic constraint in Fusion is always dense in the sense that all member constraints are created in the underlying optimization problem immediately.

Members

ConicConstraint.toString - Create a human readable representation of the constraint.

Constraint.add - Add an expression to the constraint expression.

Constraint.dual

Constraint.get_model - Get the original model object.

Constraint.get_nd - Get the number of dimensions of the constraint.

Constraint.index - Get a single element from a one-dimensional constraint.

Constraint. level - Get the primal solution value of the variable.

Constraint.shape

Constraint.size - Get the total number of elements in the constraint.

ModelConstraint.slice

Implements

 ${\it ModelConstraint}$

ret = ConicConstraint.toString()

Create a human readable representation of the constraint.

Return

•ret (string)

13.1.8 Class ConicVariable

mosek.fusion.ConicVariable

This class represents a conic variable of the form

$$Ax - b \in \mathcal{K}$$

where K is either a quadratic cone or a rotated quadratic cone. Then class is never explicitly instantiated, but is created using Model.variable by specifying a conic domain.

Note that a conic variable in *Fusion* is always *dense* in the sense that all member variables are created in the underlying optimization problem immediately.

Members

BaseVariable.antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr - Create an expression corresponding to the variable object.

BaseVariable. diag - Return the diagonal of a square variable matrix.

BaseVariable.dual - Get the dual solution value of the variable.

BaseVariable.getModel - Return the model to which the variable belongs

BaseVariable.getShape - Return the model to which the variable belongs

13.1. Class list 139

```
BaseVariable.index - Return a variable slice of size 1 corresponding to a single element in the
     variable object..
     BaseVariable. level - Get the primal solution value of the variable.
     BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any
     BaseVariable.makeInteger - Apply integrality constraints on the variable
     BaseVariable. pick - Create a slice variable by picking a list of indexes from this variable.
     BaseVariable.setLevel - Input solution values for this variable
     BaseVariable. shape - Return the shape of the variable.
     BaseVariable. size - Get the number of elements in the variable.
     BaseVariable.transpose - Transpose a vector or matrix variable
     Conic Variable. to String - Create a string-representation of the variable.
     Model Variable. slice - Create a slice variable by picking a range of indexes for each variable
     dimension
Implements
     ModelVariable
ret = ConicVariable.toString()
     Create a string-representation of the variable.
Return
```

13.1.9 Class Constraint

•ret (string)

mosek.fusion.Constraint

An abstract constraint object. This is the base class for all constraint types in Fusion.

The Constraint object can be an interface to the normal model constraint, e.g. LinearConstraint and ConicConstraint, to slices of other constraints or to concatenations of other constraints.

Primal and dual solution values can be accessed through the Constraint object.

```
Members

Constraint.add - Add an expression to the constraint expression.

Constraint.dual

Constraint.get_model - Get the original model object.

Constraint.get_nd - Get the number of dimensions of the constraint.

Constraint.index - Get a single element from a one-dimensional constraint.

Constraint.level - Get the primal solution value of the variable.

Constraint.shape

Constraint.size - Get the total number of elements in the constraint.

Constraint.slice

Constraint.toString - Create a human readable representation of the constraint.

Static Members Constraint.stack

Implemented by

CompoundConstraint, ModelConstraint, SliceConstraint
```

ret = Constraint.add(expr)
ret = Constraint.add(v)

```
ret2 = Constraint.add(cs)
ret2 = Constraint.add(c)
     Add an expression to the constraint expression.
Parameters
         •expr (Expression)
         •v (Variable)
         •cs (double[])
         •c (double)
Return
         •ret (Constraint) - The constraint itself.
         •ret2 (Constraint)
ret = Constraint.dual()
ret2 = Constraint.dual(firstidx, lastidx)
ret3 = Constraint.dual(firstidx2, lastidx2)
Parameters
         •firstidx (int32) - Index of the first element in the range.
         •lastidx (int32) - Index of the last element (inclusive) in the range.
         •firstidx2 (int32[]) - Array of indexes of the first element in each dimension.
         •lastidx2 (int32[]) – Array of indexes of the last element (inclusive) in each dimension.
Return
         •ret (double[]) - An array of values corresponding to the dual solution values of the con-
          straint.
         •ret2 (double[]) - An array of solution values.
         •ret3 (double[]) - An array of solution values. When the selected slice is multi-dimensional,
          this corresponds to the flattened slice of solution values.
ret = Constraint.get_model()
     Get the original model object.
Return
         •ret (Model) - The model to which the constraint belongs.
ret = Constraint.get_nd()
     Get the number of dimensions of the constraint.
Return
         •ret (int32) - The number of dimensions in the constraint.
ret = Constraint.index(idx)
ret = Constraint.index(idx2)
     Get a single element from a one-dimensional constraint.
Parameters
         •idx (int32) - The element index.
         •idx2 (int32[]) – Array of integers entry in each dimension.
Return
         •ret (Constraint) - A new slice containing a single element.
ret = Constraint.level()
     Get the primal solution value of the variable.
Return
         •ret (double[]) - An array of solution values. When the selected slice is multi-dimensional,
```

this corresponds to the flattened slice of solution values.

```
ret = Constraint.shape()
Return
         •ret (Set)
ret = Constraint.size()
     Get the total number of elements in the constraint.
Return
         •ret (int64) - The total numbe of elements in the constraint.
ret = Constraint.slice(first, last)
ret = Constraint.slice(first2, last2)
Parameters
         •first (int32) - Index of the first element in the slice.
         •last (int32) - Index if the last element in the slice.
         •first2 (int32[]) - Array of start elements in the slice.
         •last2 (int32[]) - Array of end element in the slice.
Return
         •ret (Constraint) - A new constraint object representing a slice of this object.
ret = Constraint.stack(v1, v2)
ret = Constraint.stack(v1, v2, v3)
ret = Constraint.stack(clist)
Parameters
         •v1 (Constraint) - The first constraint in the stack.
         •v2 (Constraint) - The second constraint in the stack.
         •v3 (Constraint) - The second constraint in the stack.
         •clist (Constraint) - The constraints in the stack.
Return
         •ret (Constraint) - An object representing the concatenation of the constraints.
ret = Constraint.toString()
     Create a human readable representation of the constraint.
Return
         •ret (string) - A string with the constraint representation.
```

13.1.10 Class Domain

mosek.fusion.Domain

The *Domain* class defines a set of static method for creating various variable and constraint domains. A *Domain* object specifies a subset of \mathbb{R}^n , which can be used to define the feasible domain of variables and expressions.

For further details on the use of these, see

```
\bullet \textit{Model.variable}
```

ullet Model.constraint

Static Members

Domain.axis - Set the dimension along which the cones are created

Domain. binary - Creates a domain of binary variables.

Domain. equals To - Defines the domain consisting of a fixed point.

```
Domain. qreaterThan – Defines the domain consisting of the half-open space bounded below by a
     value in each dimension.
     Domain. in PSDCone - Defines the domain of Positive Semidefinite matrices.
     Domain. inQCone - Defines the domain of quadratic cones
     Domain. inRange - Creates a domain representing a fixed range in any number of dimensions
     Domain. inRotatedQCone - Defines the domain of quadratic cones
     Domain.integral - Creates a domain of integral variables.
     Domain. isLinPSD - Creates a domain of Positive Semidefinite matrices.
     Domain. is TrilPSD - Creates a domain of Positive Semidefinite matrices.
     Domain. less Than - Defines the domain consisting of the half-open space bounded above by a
     value in each dimension.
     Domain.sparse – Ask to use a sparse representation
     Domain.symmetric - Impose symmetry on a given linear domain
     Domain.unbounded - Creates a domain in which variables are unbounded.
ret = Domain.axis(c, a)
     Set the dimension along which the cones are created
Parameters
         ●c (QConeDomain)
         •a (int32)
Return
         ◆ret (QConeDomain)
ret = Domain.binary(n)
ret = Domain.binary(m, n)
ret = Domain.binary(dims)
ret = Domain.binary()
     Create a domain composed by n binary variables.
Parameters
         •n (int32) - First dimension size.
         •m (int32) - Second dimension size.
         •dims (int32[]) - A list of dimension sizes.
Return
         ◆ret (RangeDomain)
ret = Domain.equalsTo(b)
ret = Domain.equalsTo(b, n)
ret = Domain.equalsTo(b, m, n)
ret = Domain.equalsTo(b, dims)
ret = Domain.equalsTo(a1)
ret = Domain.equalsTo(a2)
ret = Domain.equalsTo(a1, dims)
ret = Domain.equalsTo(mx)
     Defines the domain consisting of a fixed point.
Parameters
         •b (double) – A single value. This is scalable: For, say, a M \times N variable, it means that each
          element in the variable is fixed to b.
         •n (int32) - First dimension size.
         •m (int32) - Second dimension size.
```

- •a1 (double[]) A one-dimensional array of bounds. The size and shape must match the variable or constraint with which it is used.
- •dims (int32[]) A list of dimension sizes.
- •a2 (double[][]) A two-dimensional array of bounds. The size and shape must match the variable or constraint with which it is used.
- •mx (Matrix) A matrix of bound values. The shape must match the variable or constraint with which it is used.

Return

```
•ret (LinearDomain)
ret = Domain.greaterThan(b)
ret = Domain.greaterThan(b, n)
ret = Domain.greaterThan(b, m, n)
ret = Domain.greaterThan(b, dims)
ret = Domain.greaterThan(a1)
ret = Domain.greaterThan(a2)
ret = Domain.greaterThan(a1, dims)
ret = Domain.greaterThan(mx)
```

Defines the domain consisting of the half-open space bounded below by a value in each dimension. Parameters

- •b (double) A single value. This is scalable: For, say, a $M \times N$ variable, it means that each element in the variable is less than to b.
- •n (int32) First dimension size.
- •m (int32) Second dimension size.
- •a1 (double[])
- •dims (int32[]) A list of dimension sizes.
- •a2 (double[][])
- •mx (Matrix) A matrix of bound values. The shape must match the variable or constraint with which it is used.

Return

```
•ret (LinearDomain)
```

```
ret = Domain.inPSDCone()
ret = Domain.inPSDCone(n)
ret = Domain.inPSDCone(n, m)
```

Creates an object representing m (by default 1) cone(s) of the form:

$$\left\{ X \in \mathbb{R}^{n \times n} | \frac{1}{2} (X + X^T) \in \mathcal{S}_+^n \right\}$$

The shape of the result is $n \times n$ if m was not given, and $n \times n \times m$ if it is..

Parameters

- •n (int32) Dimension of the cone.
- •m (int32) Number of cones. By default this is 1.

Return

```
•ret (PSDDomain)
ret = Domain.inQCone()
```

ret = Domain.inQCone(n)
ret = Domain.inQCone(m, n)

ret = Domain.inQCone(dims)

Defines the domain of quadratic cones:

$$\left\{ x \in \mathbb{R}^n | x_1^2 \ge \sum_{i=2}^n x_i^2, \ x_1 \ge 0 \right\}$$

If m is given, it produces a domain defining the set if m cones of this type.

Parameters

- •n (int32) The size of each cone; at least 2.
- •m (int32) The number of cones; at least 1.
- •dims (int32[])

Return

- ●ret (QConeDomain)
- ret = Domain.inRange(lb, ub)
- ret = Domain.inRange(lb, uba)
- ret = Domain.inRange(lba, ub)
- ret = Domain.inRange(lba, uba)
- ret = Domain.inRange(lb, ubm)
- ret = Domain.inRange(lbm, ub)
- ret = Domain.inRange(lbm, ubm)

Create a domain defining a fixed lower and upper bound for each scalar element.

Note that of both upper and lower bounds are defined by a scalar, the resulting domain will scale to any size.

Parameters

- •lb (double) The lower end of the range as a common scalar value.
- •ub (double) The upper end of the range as a common scalar value.
- •lba (double[]) The lower end of the range as an array.
- •uba (double[]) The upper end of the range as an array.
- •lbm (Matrix) The lower end of the range as a Matrix object.
- •ubm (Matrix) The upper end of the range as a Matrix object.

Return

•ret (RangeDomain)

- ret = Domain.inRotatedQCone()
- ret = Domain.inRotatedQCone(n)
- ret = Domain.inRotatedQCone(m, n)
- ret = Domain.inRotatedQCone(dims)

Defines the domain of rotated quadratic cones:

$$\left\{ x \in \mathbb{R}^n | x_1 x_2 \ge \sum_{i=3}^n x_i^2, \ x_1, x_2 \ge 0 \right\}$$

If m is given, it produces a domain defining the set if m cones of this type.

Parameters

- •n (int32) The size of each cone; at least 3.
- •m (int32) The number of cones; at least 1.
- •dims (int32[])

Return

•ret (QConeDomain)

ret = Domain.integral(c)

```
ret2 = Domain.integral(ld)
ret3 = Domain.integral(rd)
     Modify a given domain restricting its elements to be integral.
Parameters
          •c (QConeDomain) - A conic quadratic domain.
          •ld (LinearDomain) - A linear domain.
          •rd (RangeDomain) - A ranged domain.
Return
          ◆ret (QConeDomain)
          •ret2 (LinearDomain)
          •ret3 (RangeDomain)
ret = Domain.isLinPSD()
ret = Domain.isLinPSD(n)
ret = Domain.isLinPSD(n, m)
      Creates an object representing the product of m cones of the form:
                                           \{X \in \mathbb{R}^{n \times n} | \operatorname{tril}(X) \in \mathcal{S}_{+}^{n} \}
     i.e. the lower triangular part of X define the symmetric matrix that is semidefinite.
     The shape of the result is n \times n \times m.
Parameters
          •n (int32) - Dimension of the cone.
          •m (int32) - Number of cones. By default this is 1.
Return
          ulletret (LinPSDDomain)
ret = Domain.isTrilPSD()
ret = Domain.isTrilPSD(n)
ret = Domain.isTrilPSD(n, m)
      Creates an object representing the product of m cones of the form:
                                           \{X \in \mathbb{R}^{n \times n} | \operatorname{tril}(X) \in \mathcal{S}_{+}^{n} \}
     i.e. the lower triangular part of X define the symmetric matrix that is semidefinite.
     The shape of the result is n \times n \times m.
Parameters
          •n (int32) - Dimension of the cone.
          •m (int32) - Number of cones. By default this is 1.
Return
          ●ret (PSDDomain)
ret = Domain.lessThan(b)
ret = Domain.lessThan(b, n)
ret = Domain.lessThan(b, m, n)
ret = Domain.lessThan(b, dims)
ret = Domain.lessThan(a1)
```

Defines the domain consisting of the half-open space bounded above by a value in each dimension. Parameters

ret = Domain.lessThan(a2)
ret = Domain.lessThan(a1, dims)
ret = Domain.lessThan(mx)

- •b (double) A single value. This is scalable: For, say, a $M \times N$ variable, it means that each element in the variable is less than to b.
- •n (int32) First dimension size.
- •m (int32) Second dimension size.
- •a1 (double[]) A one-dimensional array of bounds. The size and shape must match the variable or constraint with which it is used.
- •dims (int32[]) A list of dimension sizes.
- •a2 (double[][]) A two-dimensional array of bounds. The size and shape must match the variable or constraint with which it is used.
- \bullet mx (Matrix) A matrix of bound values. The shape must match the variable or constraint with which it is used.

Return

```
•ret (LinearDomain)
```

```
ret = Domain.sparse(ld)
```

ret2 = Domain.sparse(rd)

Given a linear domain d, this method explicitly sugest to Fusion that a sparse representation is helpful.

Parameters

- •ld (*LinearDomain*) The putative linear sparse domain
- •rd (RangeDomain) The putative ranged sparse domain

Return

- •ret (LinearDomain)
- •ret2 (RangeDomain)

ret = Domain.symmetric(ld)

ret2 = Domain.symmetric(rd)

Given a linear domain d, this method returns a domain such that

$$\{x \in D \subseteq \mathbb{R}^{N \times M} : x_{ij} = x_j i, fori = 1, \dots, N \quad j = 1, \dots, M.\}$$

Parameters

- •ld (LinearDomain) The linear domain to be modified
- •rd (RangeDomain) The ranged domain to be modified

Return

- •ret (SymmetricLinearDomain)
- •ret2 (SymmetricRangeDomain)

ret = Domain.unbounded()

ret = Domain.unbounded(n)

ret = Domain.unbounded(m, n)

ret = Domain.unbounded(dims)

Creates a domain in which variables are unbounded.

Parameters

- •n (int32) First dimension size.
- •m (int32) Second dimension size.
- •dims (int32[]) A list of dimension sizes.

Return

•ret (LinearDomain)

13.1.11 Class Expr

```
mosek.fusion.Expr
     It represents an expression of the form Ax + b, where A is a matrix on sparse form, x is a variable
     vector and b is a vector of scalars.
     Additionally, the class defines a set of static method for constructing various expressions.
     Members
     Expr. eval – Evaluate the expression info to a simple array-based form
     Expr. getModel - Return the model to which the expression belongs
     Expr. getShape - Return the shape of the expression
     Expr. index – Return a specific term of the expression
     Expr. numNonzeros - Return the number of non zero elements in the expression.
     Expr. pick - Create an expression vector by picking elements from this expression.
     Expr. shape - Returns the shape of the expression.
     Expr. size - Return the expression size
     Expr. slice - Return a slice of the expression
     Expr. toString - Create a human readable representation of the expression.
     Expr. transpose - Transpose the expression
     Static Members
     Expr. add - Construct an expression as the sum items.
     Expr. const Term - Create an expression consisting of a constant vector of values.
     Expr. dot - Return an object representing the dot-product of two values.
     Expr. flatten - Rehshape the expression into a vector
     Expr. hstack - Stack a list of expressions horizontally (i.e. along the second dimension).
     Expr. mul - Multiply two items.
     Expr. mulDiag - Compute the diagonal of the product of two matrixes and return it as a vector.
     Expr. mulElm - Element-wise multiplication of two items. The two operands must have the same
     shape.
     Expr. neg - Change the sign of an expression
     Expr. ones - Create a vector of ones as an expression.
     Expr. outer – Return an object representing the outer-product of two vectors.
     Expr. repeat - Repeart an expression a number of times in the given dimension.
     Expr. reshape - Reshape the expression into a different shape with the same number of elements.
     Expr. stack - Stack a list of expressions in an arbitrary dimension.
     Expr. sub - Construct an expression as the difference of two items.
     Expr. sum - Sum the elements of an expression
     Expr. vstack - Stack a list of expressions vertically (i.e. along the first dimension).
```

```
ret = Expr.add(e1, e2)
ret = Expr.add(e1, v2)
ret = Expr.add(v1, e2)
ret = Expr.add(e1, a1)
```

Expr. zeros - Create a vector of zeros as an expression.

```
ret = Expr.add(e1, a2)
ret = Expr.add(a1, e2)
ret = Expr.add(a2, e2)
ret = Expr.add(e1, c)
ret = Expr.add(c, e2)
ret = Expr.add(e1, m)
ret = Expr.add(m, e2)
ret = Expr.add(e1, n)
ret = Expr.add(n, e2)
ret = Expr.add(v1, v2)
ret = Expr.add(v1, a1)
ret = Expr.add(v1, a2)
ret = Expr.add(a1, v2)
ret = Expr.add(a2, v2)
ret = Expr.add(v1, c)
ret = Expr.add(c, v2)
ret = Expr.add(v1, m)
ret = Expr.add(m, v2)
ret = Expr.add(v1, n)
ret = Expr.add(n, v2)
ret = Expr.add(vs)
ret = Expr.add(exps)
```

Following combinations of operands are allowed:

А	В
Variable	Variable
Expression	Expression
double	
double[]	
double[,]	
Matrix	
NDSparseArray	

i.e. both add(A,B) and add(B,A) are available.

Note that the size and shape of the operand matter and must adhere to the rules of matrix multiplication.

Parameters

```
•e1 (Expression) - An expression.
```

- •e2 (Expression) An expression.
- •a1 (double[]) A one-dimensional array of constants.
- •a2 (double[][]) A two-dimensional array of constants.
- •c (double) A constant.
- •m (Matrix) A Matrix object.
- •n (NDSparseArray) An NDSparseArray object.
- •v1 (Variable) An variable.
- •v2 (Variable) An variable.
- •vs (Variable) A list of Variables. All variables in the array must have the same shape and size. The list must contain at least one element.
- •exps (Expression) A list of expressions. All expressions in the array must have the same size. The list must contain at least one element.

Return

•ret (Expression)

```
ret = Expr.constTerm(vals1)
ret2 = Expr.constTerm(vals2)
ret = Expr.constTerm(size, val)
ret2 = Expr.constTerm(shp, val2)
ret2 = Expr.constTerm(val2)
ret2 = Expr.constTerm(m)
ret2 = Expr.constTerm(nda)
      Create an expression consisting of a constant vector of values.
Parameters
         •vals1 (double[]) - Values to put in vector
         •vals2 (double[][])
         •size (int32) - Length of the vector
         •val (double) - Value to put in vector
         •shp (Set) - Defines the shape of the expression
         •val2 (double) - A scalar value to put in vector or matrix expression
         •m (Matrix) - A Matrix of values to put in the expression
         •nda (NDSparseArray) - An n-dimensional sparse array of values to put in the expression
Return
         •ret (Expression) - An expression representing a vector.
         •ret2 (Expression)
ret = Expr.dot(v, a1)
ret = Expr.dot(v, a2)
\mathtt{ret} = \mathtt{Expr.dot}(\mathtt{v}, \mathtt{m})
ret = Expr.dot(v, spm)
ret = Expr.dot(expr, spm)
ret = Expr.dot(expr, a1)
ret = Expr.dot(expr, a2)
ret = Expr.dot(expr, m)
ret = Expr.dot(a1, expr)
ret = Expr.dot(a1, v)
ret = Expr.dot(a2, expr)
ret = Expr.dot(a2, v)
ret = Expr.dot(spm, expr)
ret = Expr.dot(spm, v)
\mathtt{ret} = \mathtt{Expr.dot}(\mathtt{m},\,\mathtt{v})
ret = Expr.dot(m, expr)
     Return an object representing the inner product ("dot product") of two vectors, i.e. the sum of the
     element-wise multiplication.
Parameters
         •v (Variable) - A variable object.
         •a1 (double[]) - A one-dimensional coefficient array.
         •m (Matrix) - A matrix object.
         •spm (NDSparseArray) - A multidimensional sparse array object.
         •a2 (double[][]) - A two-dimensional coefficient array.
         •expr (Expression) - An expression object.
Return
         •ret (Expression)
ret = Expr.eval()
     Evaluate the expression info to a simple array-based form
```

```
Return
         ●ret (FlatExpr)
ret = Expr.flatten(e)
     Rehshape the expression into a vector
Parameters
         ●e (Expression)
Return
         ●ret (Expression)
ret = Expr.getModel()
     Return the model to which the expression belongs
Return
         •ret (Model)
ret = Expr.getShape()
     Return the shape of the expression
Return
         •ret (Set)
ret = Expr.hstack(exprs)
ret = Expr.hstack(e1, e2)
ret = Expr.hstack(e1, a2)
ret = Expr.hstack(e1, v2)
ret = Expr.hstack(a1, v2)
ret = Expr.hstack(a1, e2)
ret = Expr.hstack(v1, a2)
ret = Expr.hstack(v1, v2)
ret = Expr.hstack(v1, e2)
ret = Expr.hstack(a1, a2, v3)
ret = Expr.hstack(a1, a2, e3)
ret = Expr.hstack(a1, v2, a3)
ret = Expr.hstack(a1, v2, v3)
ret = Expr.hstack(a1, v2, e3)
ret = Expr.hstack(a1, e2, a3)
ret = Expr.hstack(a1, e2, v3)
ret = Expr.hstack(a1, e2, e3)
ret = Expr.hstack(v1, a2, a3)
ret = Expr.hstack(v1, a2, v3)
ret = Expr.hstack(v1, a2, e3)
ret = Expr.hstack(v1, v2, a3)
ret = Expr.hstack(v1, v2, v3)
ret = Expr.hstack(v1, v2, e3)
ret = Expr.hstack(v1, e2, a3)
ret = Expr.hstack(v1, e2, v3)
ret = Expr.hstack(v1, e2, e3)
ret = Expr.hstack(e1, a2, a3)
ret = Expr.hstack(e1, a2, v3)
ret = Expr.hstack(e1, a2, e3)
ret = Expr.hstack(e1, v2, a3)
ret = Expr.hstack(e1, v2, v3)
ret = Expr.hstack(e1, v2, e3)
ret = Expr.hstack(e1, e2, a3)
ret = Expr.hstack(e1, e2, v3)
\mathtt{ret} = \mathtt{Expr.hstack(e12,\,e22,\,e32)}
```

All expressions must have the same shape, except for the second dimension. If expressions are

```
e1, e2, e3, ...
```

then

```
dim(e1,1) = dim(e2,1) = dim(e3,1) = ...
dim(e1,3) = dim(e2,3) = dim(e3,3) = ...
...
```

and the dimension of the result is

```
dim(e1,1),
(dim(e1,2) + dim(e2,2) + ...,
dim(e1,3),
...)
```

The arguments may be any combination of expressions, scalar constants and variables.

Parameters

- •exprs (Expression) A list of expressions.
- •e1 (Expression) An expression, a scalar constant or a variable.
- •e2 (Expression) An expression, a scalar constant or a variable.
- •v3 (Variable) A variable.
- •a1 (double) A scalar constant.
- ulleta2 (double) a scalar constant.
- •e3 (Expression) An expression, a scalar constant or a variable.
- •v1 (Variable) A variable.
- •v2 (Variable) A variable.
- •a3 (double) a scalar constant.
- •e12 (Expression) An expression object.
- •e22 (Expression) An expression object.
- •e32 (Expression) An expression object.

Return

```
●ret (Expression)
```

```
ret = Expr.index(first)
ret = Expr.index(firsta)
```

Given an expression object e or a variable object v it returns a new expression -e and -v respectively.

Parameters

- •first (int32) The index of the terms.
- $\bullet \texttt{firsta}$ (int32[]) The indexs of the terms.

Return

```
•ret (Expression)
```

```
ret = Expr.mul(mx, v)
```

ret2 = Expr.mul(v, mx)

ret = Expr.mul(v, vals)

ret = Expr.mul(vals, v)

 $\mathtt{ret} = \mathtt{Expr.mul}(\mathtt{val},\,\mathtt{v})$

ret = Expr.mul(v, val)

ret = Expr.mul(vals2, v)

 ${\tt ret} = {\tt Expr.mul(v, vals2)}$

```
ret = Expr.mul(expr, val)
ret = Expr.mul(val, expr)
ret3 = Expr.mul(vals, expr)
ret = Expr.mul(expr, vals)
ret = Expr.mul(expr, mx)
ret = Expr.mul(mx, expr)
```

Following combinations of operands are allowed:

Α	В
double	Variable
double[]	Expression
double[,]	
Matrix	

i.e. both mul(A,B) and mul(B,A) are available.

Note that the size and shape of the operand matter and must adhere to the rules of matrix multiplication.

Parameters

```
•mx (Matrix) - A matrix.
```

- •v (Variable) A variable object that may be a scalar or a matrix.
- •val (double) A scalar value.
- •vals2 (double[][])
- •vals (double[]) A vector of scalars.
- •expr (Expression) An expression object. The shape must match the right-hand side.

Return

- •ret (Expression)
- •ret2 (Expression) A new expression object representing the product of the two operands.
- •ret3 (Expression) A new expression.

```
ret = Expr.mulDiag(a, expr)
ret = Expr.mulDiag(expr, a)
```

 $\mathtt{ret} = \mathtt{Expr.mulDiag}(\mathtt{a},\,\mathtt{v})$

ret = Expr.mulDiag(v, a)

 ${\tt ret2} = {\tt Expr.mulDiag(mx,\,expr2)}$

ret2 = Expr.mulDiag(expr2, mx)

 ${\tt ret2} = {\tt Expr.mulDiag(mx2,\,v)}$

 ${\tt ret2} = {\tt Expr.mulDiag(v2,\,mx)}$

Compute the diagonal of the product of two matrixes, $A \in \mathbb{M}(m,n)$ and $B \in \mathbb{M}(n,p)$. This amounts to a vector $v = (v_1, \ldots, v_n)$ where $v_i = a_i^t b_{i}$.

Parameters

- $\bullet \texttt{a} \; (\texttt{double[][]})$
- •expr (Expression) An expression object.
- •mx (Matrix) An $m \times n$ matrix object.
- •expr2 (*Expression*) An $n \times p$ expression object.
- •mx2 (Matrix) An matrix object.
- •v (Variable) A variable object.
- •v2 (*Variable*) An $n \times p$ variable object.

Return

- ●ret (Expression)
- •ret2 (Expression) A new Expr object.

```
ret = Expr.mulElm(v, a1)
ret = Expr.mulElm(v, a2)
ret = Expr.mulElm(v, spm)
ret = Expr.mulElm(v, m)
ret = Expr.mulElm(expr, spm)
ret = Expr.mulElm(expr, a1)
ret = Expr.mulElm(expr, a2)
ret = Expr.mulElm(expr, m)
ret = Expr.mulElm(a1, expr)
ret = Expr.mulElm(a1, v)
ret = Expr.mulElm(a2, expr)
ret = Expr.mulElm(a2, v)
ret = Expr.mulElm(spm, expr)
ret = Expr.mulElm(spm, v)
ret = Expr.mulElm(m, v)
ret = Expr.mulElm(m, expr)
     Element-wise multiplication of two items. The two operands must have the same shape.
Parameters
         •v (Variable) - A variable object.
         •a1 (double[]) - A one-dimensional coefficient array.
         •spm (NDSparseArray) - A multidimensional sparse array object.
         •m (Matrix) - A matrix object.
         •a2 (double[][]) - A two-dimensional coefficient array.
         •expr (Expression) - An expression object.
Return
         •ret (Expression)
ret = Expr.neg(e)
ret = Expr.neg(v)
     Given an expression object e or a variable object v it returns a new expression -e and -v respec-
     tively.
Parameters
         •e (Expression) - An expression object.
         •v (Variable) - A variable object.
Return
         •ret (Expression)
ret = Expr.numNonzeros()
     Return the number of non zero elements in the expression.
Return
         •ret (int64) – The number of non zero elements.
ret = Expr.ones(num)
     Create a vector of ones as an expression.
Parameters
         •num (int32) – The size of the expression.
Return
         •ret (Expression) - An expression representing a vector of ones.
ret = Expr.outer(v, a)
ret = Expr.outer(a, v)
ret = Expr.outer(e, a)
ret = Expr.outer(a, e)
     Return an object representing the outer product of two vectors.
```

```
Parameters
         •v (Variable) - A vector or matrix variable
         •a (double[]) - A vector of constants
         •e (Expression) - A vector expression
Return
```

```
•ret (Expression)
```

```
ret = Expr.pick(indexes)
ret = Expr.pick(indexrows)
```

Create an expression vector by picking elements from this expression.

Parameters

- •indexes (int32[]) A list of integers specifying which indexes to take from an onedimensional Expression.
- •indexrows (int32[][]) A $n \times m$ array of integers where each row specifies an m-dimensional index to pick.

Return

```
●ret (Expression)
```

```
ret = Expr.repeat(e, n, d)
```

Repeart an expression a number of times in the given dimension.

Parameters

- •e (Expression) The expression to repeat.
- •n (int32) Number of time to repeat. Must be strictly positive.
- •d (int32) The dimension in which to repeat. Must define a valid dimension index.

Return

```
●ret (Expression)
```

```
ret = Expr.reshape(e, shp)
ret = Expr.reshape(e, size)
ret = Expr.reshape(e, dimi, dimj)
```

Reshape the expression into a different shape with the same number of elements.

Parameters

- •e (*Expression*) The expression to reshape.
- •shp (Set) The new shape of the expression; this must have the same total size as the old shape.
- •size (int32) Reshape into a one-dimensional expression of this size.
- •dimi (int32) The first dimension size.
- •dimj (int32) The second dimension size.

Return

```
●ret (Expression)
```

```
ret = Expr.shape()
```

Returns the shape of the expression.

Return

```
•ret (Set)
```

ret = Expr.size()

Return the expression size

Return

•ret (int64) - The expression size.

ret = Expr.slice(first, last)

```
ret = Expr.slice(firsta, lasta)
     Return a slice of the expression
Parameters
         •first (int32) – The index from which the slice begins.
         •last (int32) - The index after the last elements of the slice.
         •firsta (int32[]) – The indexs from which the slice begins.
         •lasta (int32[]) - The indexs after the last elements of the slice.
Return
         •ret (Expression)
ret = Expr.stack(dim, exprs)
ret = Expr.stack(dim, e1, e2)
ret = Expr.stack(dim, e1, a2)
ret = Expr.stack(dim, e1, v2)
\mathtt{ret} = \mathtt{Expr.stack}(\mathtt{dim},\,\mathtt{a1},\,\mathtt{v2})
ret = Expr.stack(dim, a1, e2)
ret = Expr.stack(dim, v1, a2)
ret = Expr.stack(dim, v1, v2)
ret = Expr.stack(dim, v1, e2)
ret = Expr.stack(dim, a1, a2, v1)
ret = Expr.stack(dim, a1, a2, e1)
ret = Expr.stack(dim, a1, v2, a3)
ret = Expr.stack(dim, a1, v2, v3)
ret = Expr.stack(dim, a1, v2, e3)
ret = Expr.stack(dim, a1, e2, a3)
ret = Expr.stack(dim, a1, e2, v3)
ret = Expr.stack(dim, a1, e2, e3)
ret = Expr.stack(dim, v1, a2, a3)
ret = Expr.stack(dim, v1, a2, v3)
ret = Expr.stack(dim, v1, a2, e3)
ret = Expr.stack(dim, v1, v2, a3)
ret = Expr.stack(dim, v1, v2, v3)
ret = Expr.stack(dim, v1, v2, e3)
ret = Expr.stack(dim, v1, e2, a3)
ret = Expr.stack(dim, v1, e2, v3)
ret = Expr.stack(dim, v1, e2, e3)
ret = Expr.stack(dim, e1, a2, a3)
ret = Expr.stack(dim, e1, a2, v3)
ret = Expr.stack(dim, e1, a2, e3)
ret = Expr.stack(dim, e1, v2, a3)
ret = Expr.stack(dim, e1, v2, v3)
ret = Expr.stack(dim, e1, v2, e3)
ret = Expr.stack(dim, e1, e2, a3)
ret = Expr.stack(dim, e1, e2, v3)
ret = Expr.stack(dim, e1, e2, e3)
ret = Expr.stack(exprs2)
     All expressions must have the same shape, except for dimension dim. If expressions are
     The arguments may be any combination of expressions, scalar constants and variables.
Parameters
         •dim (int32)
         •exprs (Expression) - A list of expressions.
         •e1 (Expression) – An expression, a scalar constant or a variable.
         •e2 (Expression) – An expression, a scalar constant or a variable.
```

```
•a3 (double) - a scalar constant.
         •v3 (Variable) - A variable.
         •e3 (Expression) - An expression, a scalar constant or a variable.
         •v2 (Variable) - A variable.
         •a1 (double) - A scalar constant.
         •a2 (double) - a scalar constant.
         •v1 (Variable) - A variable.
         •exprs2 (Expression) - A list of expressions.
Return
         ●ret (Expression)
ret = Expr.sub(e1, e2)
ret = Expr.sub(e1, v2)
ret = Expr.sub(v1, e2)
ret = Expr.sub(e1, a1)
ret = Expr.sub(e1, a2)
ret = Expr.sub(a1, e2)
ret = Expr.sub(a2, e2)
ret = Expr.sub(e1, c)
ret = Expr.sub(c, e2)
ret = Expr.sub(e1, m)
ret = Expr.sub(m, e2)
ret = Expr.sub(e1, n)
ret = Expr.sub(n, e2)
ret = Expr.sub(v1, v2)
ret = Expr.sub(v1, a1)
ret = Expr.sub(v1, a2)
ret = Expr.sub(a1, v2)
ret = Expr.sub(a2, v2)
ret = Expr.sub(v1, c)
ret = Expr.sub(c, v2)
ret = Expr.sub(v1, m)
ret = Expr.sub(m, v2)
ret = Expr.sub(v1, n)
```

A	Ь
Variable	Variable
Expression	Expression
double	
double[]	
double[,]	
Matrix	

ret = Expr.sub(n, v2)

NDSparseArray

Λ

i.e. both sub(A,B) and sub(B,A) are available.

Following combinations of operands are allowed:

В

Note that the size and shape of the operand matter and must adhere to the rules of matrix multiplication.

Parameters

- •e1 (Expression) An expression.
- •e2 (Expression) An expression.
- •a1 (double[]) An array of constants.

```
•a2 (double[][]) - An array of constants.
         •c (double)
         •m (Matrix)
         •n (NDSparseArray)
         •v1 (Variable) - An variable.
         •v2 (Variable) - An variable.
Return
         •ret (Expression)
ret = Expr.sum(expr)
\mathtt{ret} = \mathtt{Expr.sum}(\mathtt{v})
ret = Expr.sum(v, d)
ret = Expr.sum(v, dfirst, dlast)
ret = Expr.sum(expr, d)
ret = Expr.sum(expr, dfirst, dlast)
     Sum the elements of an expression. Without extra arguments, all elements are summed into an
     expression of size 1.
     With arguments dfirst, dlast or d, elements are summed in a specific dimension or a range of
     dimensions, resulting in an expression of reduced dimension.
     Note that the result of summing over a dimension of size 0 is 0.0. This means that for an expression
     of shape (2,0,2), summing over the second dimension yields an expression of shape (2,2) of zeros.
Parameters
         •expr (Expression) - An expression object.
         •d (int32) - The dimension to sum.
         •v (Variable) - An variable.
         •dfirst (int32) - The first dimension to sum.
         •dlast (int32) – The last-plus-one dimension to sum.
Return
         •ret (Expression)
ret = Expr.toString()
     Create a human readable representation of the expression.
Return
         •ret (string) - A string with the representation expression.
ret = Expr.transpose()
     Transpose the expression
Return
         •ret (Expression)
ret = Expr.vstack(exprs)
ret = Expr.vstack(e1, e2)
ret = Expr.vstack(e1, v2)
ret = Expr.vstack(e1, a2)
ret = Expr.vstack(v1, e2)
ret = Expr.vstack(v1, v2)
ret = Expr.vstack(v1, a2)
ret = Expr.vstack(a1, e2)
ret = Expr.vstack(a1, v2)
ret = Expr.vstack(e1, e2, e3)
ret = Expr.vstack(e1, e2, v3)
```

ret = Expr.vstack(e1, e2, a3)

```
ret = Expr.vstack(e1, v2, e3)
ret = Expr.vstack(e1, v2, v3)
ret = Expr.vstack(e1, v2, a3)
ret = Expr.vstack(e1, a2, e3)
ret = Expr.vstack(e1, a2, v3)
ret = Expr.vstack(e1, a2, a3)
ret = Expr.vstack(v1, e2, e3)
ret = Expr.vstack(v1, e2, v3)
ret = Expr.vstack(v1, e2, a3)
ret = Expr.vstack(v1, v2, e3)
ret = Expr.vstack(v1, v2, v3)
ret = Expr.vstack(v1, v2, a3)
ret = Expr.vstack(v1, a2, e3)
ret = Expr.vstack(v1, a2, v3)
ret = Expr.vstack(v1, a2, a3)
ret = Expr.vstack(a1, e2, e3)
ret = Expr.vstack(a1, e2, v3)
ret = Expr.vstack(a1, e2, a3)
ret = Expr.vstack(a1, v2, e3)
ret = Expr.vstack(a1, v2, v3)
ret = Expr.vstack(a1, v2, a3)
ret = Expr.vstack(a1, a2, e3)
ret = Expr.vstack(a1, a2, v3)
ret = Expr.vstack(a1, a2, a3)
     The expressions must have the same shape, except for the first dimension. If expressions are
     e1, e2
     then
     dim(e1,2) = dim(e2,2)
     dim(e1,3) = dim(e2,3)
     and the dimension of the result is
     (\dim(e1,1) + \dim(e2,1)
      dim(e1,2),
      dim(e1,3),
      ...)
     The arguments may be any combination of expressions, scalar constants and variables.
Parameters
         •exprs (Expression) - A list of expressions.
         •e1 (Expression) - An expression, a scalar constant or a variable.
         •e2 (Expression) – An expression, a scalar constant or a variable.
         •e3 (Expression) – An expression, a scalar constant or a variable.
         •v1 (Variable) - A variable.
         •v2 (Variable) - A variable.
         •v3 (Variable) - A variable.
         •a1 (double) - A scalar constant.
         •a2 (double) - a scalar constant.
         •a3 (double) - a scalar constant.
Return
```

•ret (Expression)

```
ret = Expr.zeros(num)
     Create a vector of zeros as an expression.
Parameters
         •num (int32) - The size of the expression.
Return
         •ret (Expression) - An expression representing a vector of zeros.
13.1.12 Class Expression
mosek.fusion.Expression
     Abstract base class for all objects which can be used as linear expressions of the form Ax + b.
     The main use of this class is to store the result of expressions created by the static methods provided
     by Expr.
     Members
     Expression.eval – Evaluate the expression into simple sparse form.
     Expression.getModel - Return the Model object.
     Expression. getShape - Initialize the expression as belonging to a given model.
     Expression. index - Get a single element of the expression
     Expression.pick - Get a list of elements of the expression
     Expression. shape - Returns the shape of the expression.
     Expression.slice
     Expression. to String - Return a string representation of the expression object.
     Expression. transpose - Transpose the expression
Implemented by
     Expr
ret = Expression.eval()
     Evaluate the expression into simple sparse form.
Return
         •ret (FlatExpr) - The evaluated expression.
ret = Expression.getModel()
     Return the Model object.
Return
         •ret (Model) - The Model object.
ret = Expression.getShape()
     Initialize the expression as belonging to a given model.
Return
         •ret (Set)
ret = Expression.index(i)
ret2 = Expression.index(indexes)
     Get a single element of the expression
Parameters
         •i (int32) - Index of the element to pick
         •indexes (int32[]) - List of indexes of the element to pick
Return
         •ret (Expression) - A new expression object.
```

```
•ret2 (Expression)
{\tt ret} = {\tt Expression.pick(indexes)}
ret = Expression.pick(indexrows)
     Get a list of elements of the expression
Parameters
         •indexes (int32[]) - Indexes of the elements to pick
         •indexrows (int32[][]) - Indexes of the elements to pick. Each row defines a separate index.
Return
         •ret (Expression) - A one dimensional expression object.
ret = Expression.shape()
     Returns the shape of the expression.
Return
         •ret (Set) - A shape object
ret = Expression.slice(firsta, lasta)
ret2 = Expression.slice(first, last)
Parameters
         •firsta (int32[]) - Start of the slice in each dimension
         •lasta (int32[]) - Env of the slice in each dimension
         •first (int32) - Start of the slice
         •last (int32) - Env of the slice
Return
         •ret (Expression) - A one dimensional expression object.
         •ret2 (Expression) - A new expression object.
ret = Expression.toString()
     Return a string representation of the expression object.
Return
         •ret (string) – A string representation of the object.
ret = Expression.transpose()
     Transpose the expression
Return
         •ret (Expression) - A new expression object.
13.1.13 Class FlatExpr
mosek.fusion.FlatExpr
     Defines a simple structure containing a sparse representation of a linear expression; basically the
     result of evaluating an Expression object.
     Members
     FlatExpr. size - Get the number of non-zero elements in the expression.
     FlatExpr. toString - Create a human readable representation of the expression.
ret = FlatExpr.size()
     Get the number of non-zero elements in the expression.
```

•ret (int32) – The number of non-zero elements in the expression.

Create a human readable representation of the expression.

Return

ret = FlatExpr.toString()

Return

•ret (string) - A string with the representation expression.

13.1.14 Class LinPSDDomain

mosek.fusion.LinPSDDomain

Represent a linear PSD domain.

13.1.15 Class LinearConstraint

mosek.fusion.LinearConstraint

A linear constraint defines a block of constraints with the same linear domain. The domain is either a product of product of one-dimensional half-spaces (linear inequalities), a fixed value vector (equalities) or the whole space (free constraints).

The *type* of a linear variable is immutable; it is either free, an inequality or an equality, but the linear expression and the right-hand side can be modified.

The class is not meant to be instantiated directly, but must be created by calling the <code>Model.variable</code> method.

Members

```
Constraint.add - Add an expression to the constraint expression.
```

Constraint.dual

Constraint.get_model - Get the original model object.

Constraint.get_nd - Get the number of dimensions of the constraint.

Constraint.index - Get a single element from a one-dimensional constraint.

 ${\it Constraint.level}$ — Get the primal solution value of the variable.

Constraint.shape

Constraint.size - Get the total number of elements in the constraint.

ModelConstraint.slice

ModelConstraint.toString - Create a human readable representation of the constraint.

Implements

 ${\it ModelConstraint}$

13.1.16 Class LinearDomain

mosek.fusion.LinearDomain

Represent a domain defined by linear constraints

Members

LinearDomain.integral - Creates a domain of integral variables.

LinearDomain.sparse - Creates a domain exploiting sparsity.

LinearDomain.symmetric - Creates a symmetric domain

${\tt ret} = {\tt LinearDomain.integral}$

Creates a domain of integral variables.

Return

```
•ret (LinearDomain)
```

•ret (SymmetricLinearDomain)

13.1.17 Class LinearPSDConstraint

mosek.fusion.LinearPSDConstraint

This class represents a semidefinite conic constraint of the form

$$Ax - b \succeq 0$$

i.e. Ax - b must be positive semidefinite

Members

Constraint.add – Add an expression to the constraint expression.

 ${\it Constraint.dual}$

 ${\it Constraint.get_model}$ — Get the original model object.

Constraint.get_nd - Get the number of dimensions of the constraint.

Constraint.index - Get a single element from a one-dimensional constraint.

Constraint.level - Get the primal solution value of the variable.

Constraint.shape

Constraint.size - Get the total number of elements in the constraint.

LinearPSDConstraint.toString - Create a human readable representation of the constraint.

ModelConstraint.slice

Implements

 ${\it ModelConstraint}$

ret = LinearPSDConstraint.toString()

Create a human readable representation of the constraint.

Return

•ret (string)

13.1.18 Class LinearPSDVariable

mosek.fusion.LinearPSDVariable

This class represents a positive semidefinite variable.

Members

Base Variable. antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr - Create an expression corresponding to the variable object.

BaseVariable.diag - Return the diagonal of a square variable matrix.

BaseVariable. dual - Get the dual solution value of the variable.

BaseVariable.getModel - Return the model to which the variable belongs

BaseVariable.getShape - Return the model to which the variable belongs

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable. level - Get the primal solution value of the variable.

BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any

BaseVariable.makeInteger - Apply integrality constraints on the variable

Base Variable. pick - Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel - Input solution values for this variable

BaseVariable. shape - Return the shape of the variable.

BaseVariable. size - Get the number of elements in the variable.

BaseVariable. transpose - Transpose a vector or matrix variable

LinearPSDVariable.toString - Create a string-representation of the variable.

ModelVariable.slice - Create a slice variable by picking a range of indexes for each variable dimension

Implements

ModelVariable

ret = LinearPSDVariable.toString()

Create a string-representation of the variable.

Return

•ret (string)

13.1.19 Class LinearVariable

mosek.fusion.LinearVariable

A linear variable defines a block of variables with the same linear domain. The domain is either a product of product of one-dimensional half-spaces (linear inequalities), a fixed value vector (equalities) or the whole space (free variables).

The type of a linear variable is immutable; it is either free, an inequality or an equality.

The class is not meant to be instantiated directly, but must be created by calling the <code>Model.variable</code> method.

Members

BaseVariable.antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr - Create an expression corresponding to the variable object.

BaseVariable.diag - Return the diagonal of a square variable matrix.

BaseVariable.dual - Get the dual solution value of the variable.

 ${\it BaseVariable.getModel}$ — Return the model to which the variable belongs

BaseVariable.getShape - Return the model to which the variable belongs

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable. level - Get the primal solution value of the variable.

BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any

BaseVariable.makeInteger - Apply integrality constraints on the variable

Base Variable. pick - Create a slice variable by picking a list of indexes from this variable.

```
BaseVariable.setLevel - Input solution values for this variable
     BaseVariable. shape - Return the shape of the variable.
     BaseVariable.size - Get the number of elements in the variable.
     BaseVariable. toString - Create a string-representation of the variable.
     Base Variable. transpose - Transpose a vector or matrix variable
     ModelVariable.slice - Create a slice variable by picking a range of indexes for each variable
     dimension
Implements
     ModelVariable
13.1.20 Class Matrix
mosek.fusion.Matrix
     Base class for all matrix objects.
     Members
     Matrix.get - Get non-zero at position (i,j).
     Matrix.getDataAsArray - Return the data a dense array of values.
     Matrix.getDataAsTriplets - Return the matrix data in triplet format.
     Matrix. isSparse - Returns true if the matrix is sparse.
     Matrix.numColumns - Returns the number columns in the matrix.
     Matrix. numNonzeros - Returns the number of non-zeros in the matrix.
     Matrix. numRows - Returns the number rows in the matrix.
     Matrix. toString - Get a string representation of the matrix.
     Matrix. transpose - Transpose the matrix.
     Static Members
     Matrix.antidiag - Create a sparse square matrix with a given vector as anti-diagonal
     Matrix.dense - Create a sparse square matrix with a given vector as anti-diagonal
     Matrix. diag - Create a sparse square matrix with a given vector as diagonal
     Matrix. eye - Create the identity matrix.
     Matrix. ones - Create a matrix filled with all ones.
     Matrix.sparse - Create a sparse square matrix with a given vector as anti-diagonal
ret = Matrix.antidiag(d)
ret = Matrix.antidiag(d, k)
ret = Matrix.antidiag(n, val)
ret = Matrix.antidiag(n, val, k)
     Create a sparse square matrix with a given vector as anti-diagonal
Parameters
         •d (double[]) - The diagonal vector
         •k (int32) – The diagonal index. k=0 is the default and means the main diagonal. k>0
          means diagonals above the main, and k < 0 means the diagonals below the main.
         •n (int32) – The size of each side in the matrix.
         •val (double) - Use this value for all diagonal elements.
```

Return

```
•ret (Matrix)
ret = Matrix.dense(data)
ret = Matrix.dense(dimi, dimj, data2)
ret = Matrix.dense(dimi, dimj, value)
\mathtt{ret} = \mathtt{Matrix.dense}(\mathtt{other})
     Create a sparse square matrix with a given vector as anti-diagonal
Parameters
         •data (double[][]) - A one- or two-dimensional array of matrix coefficients.
         •dimi (int32) - Number of rows in matrix.
         •dimj (int32) - Number of columns in matrix.
         •data2 (double[]) - A one- or two-dimensional array of matrix coefficients.
         •value (double) – Use this value for all elements.
         •other (Matrix) - Create a dense matrix from another matrix.
Return
         ●ret (Matrix)
ret = Matrix.diag(d)
ret = Matrix.diag(d, k)
ret = Matrix.diag(n, val)
ret = Matrix.diag(n, val, k)
ret2 = Matrix.diag(md)
ret = Matrix.diag(num, mv)
     Create a sparse square matrix with a given vector as diagonal
Parameters
         •d (double[]) - The diagonal vector
         •k (int32) – The diagonal index. k=0 is the default and means the main diagonal. k>0
          means diagonals above the main, and k < 0 means the diagonals below the main.
         •n (int32) – The size of each side in the matrix.
         •val (double) - Use this value for all diagonal elements.
         •md (Matrix) - A list of square matrixes that are used to create a block-diagonal square matrix.
         •num (int32) - Number of times to repeat the mv matrix.
         •mv (Matrix)
Return
         •ret (Matrix)
         •ret2 (Matrix) - A sparse block diagonal matrix.
ret = Matrix.eye(n)
     Create the identity matrix.
Parameters
         •n (int32)
Return
         •ret (Matrix) - The identity matrix of size n.
ret = Matrix.get(i, j)
     Get non-zero at position (i,j).
Parameters
         •i (int32)
         •j (int32)
Return
```

```
•ret (double)
ret = Matrix.getDataAsArray()
     Return the data a dense array of values.
Return
         •ret (double[])
ret = Matrix.getDataAsTriplets(subi, subj, val)
     Return the matrix data in triplet format.
Parameters
         •subi (int32[]) – Row subscripts are returned in this array.
         •subj (int32[]) - Column subscripts are returned in this array.
         •val (double[]) - Coefficient values are returned in this arary.
Return
         •ret (void)
ret = Matrix.isSparse()
     Returns true if the matrix is sparse.
Return
         •ret (bool)
ret = Matrix.numColumns()
     Returns the number columns in the matrix.
Return
         •ret (int32) - The number of columns.
ret = Matrix.numNonzeros()
     Returns the number of non-zeros in the matrix.
Return
         •ret (int64) - The number of non-zeros.
ret = Matrix.numRows()
     Returns the number rows in the matrix.
Return
         •ret (int32) - The number of rows.
ret = Matrix.ones(n, m)
     Create a matrix filled with all ones.
Parameters
         •n (int32)
         •m (int32)
Return
         •ret (Matrix) - An n \times m matrix filed by ones.
ret = Matrix.sparse(nrow, ncol, subi, subj, val)
ret = Matrix.sparse(subi, subj, val)
ret = Matrix.sparse(subi, subj, val2)
ret = Matrix.sparse(nrow, ncol, subi, subj, val2)
ret = Matrix.sparse(nrow, ncol)
ret = Matrix.sparse(data)
ret = Matrix.sparse(blocks)
ret = Matrix.sparse(mx)
     Create a sparse square matrix with a given vector as anti-diagonal
Parameters
         •nrow (int32)
```

•ncol (int32)

```
•subi (int32[]) - Row subscripts of non-zero elements.
         •subj (int32[]) - Column subscripts of non-zero elements.
         •val (double[]) - Coefficients of non-zero elements.
         •val2 (double) - Coefficients of non-zero elements.
         •data (double[][]) - Dense data array.
         •blocks (Matrix) - The matrix data. This is a two-dimensional array of Matrix objects or
          NULL. In blocks, all elements in a row must have the same height, and all elements in a
          column must have the same width.
          Entries that are NULL will be interpreted as a block of zeros whose height and width are
          deduced from the other elements in the same row and column. Any row that contains only
          NULL entries will have height 0, and any column that contains only NULL entries will have
         •mx (Matrix) - A Matrix object
Return
         •ret (Matrix)
ret = Matrix.toString()
     Get a string representation of the matrix.
Return
         •ret (string) - A string representation of the matrix.
ret = Matrix.transpose()
     Transpose the matrix.
Return
         •ret (Matrix)
13.1.21 Class Model
mosek.fusion.Model
     The object containing all data related to a single optimization model.
     Members
     Model.acceptedSolutionStatus - Get or set the accepted solution status.
     Model. addConstraint - Add a set of constraints to one that is already in the model.
     Model.addVariable - Add a set of variable to one that is already in the model.
     Model.breakSolver - Request that the solver terminates as soon as possible.
     Model.clone - Clone the model.
     Model. constraint - Create a new constraint in the model.
     Model. dispose - Destroy the Model object
     Model. dual Obj Value - Get the dual objective value.
     Model.flushSolutions - If any solution values have been inputted, flush those values to the
     underlying task.
     Model.getAcceptedSolutionStatus - Get the the accepted solution status.
     Model.qetConstraint - Get the constraint corresponding to the given name or index
```

Model.getName - Return the model name, or an empty string if it has not been set.

Model.getDualSolutionStatus

```
Model.getPrimalSolutionStatus
     Model.getProblemStatus - Return the problem status
     Model.getSolverDoubleInfo - Fetch a solution information item from the solver
     Model.getSolverIntInfo - Fetch a solution information item from the solver
     Model.getSolverLIntInfo - Fetch a solution information item from the solver
     Model.getTask - Return the underlying MOSEK task object.
     Model.getVariable - Get the variable corresponding to the given name or index
     Model.hasConstraint - Return whether the model contains a constraint with a given name.
     Model.hasVariable - Return whether the model contains a variable with a given name.
     Model.numConstraints - Return the number of constraints
     Model.numVariables - Return the number of variables
     Model.objective - Replace the objective expression.
     Model.primalObjValue - Get the primal objective value.
     Model.selectedSolution - Set which solution to take values from.
     Model.setCallbackHandler - Attach a callback handler.
     Model.setLogHandler - Attach a log handler.
     Model.setSolverParam - Set a solver parameter
     Model.solve - Attempt to optimize the model.
     Model.variable - Create a new variable in the model.
     Model.writeTask - Dump the current solver task to a file.
     Static Members
     Model.putlicensecode - Set the license code in the global environment
     Model.putlicensepath - Set the license path in the global environment
     Model.putlicensewait - Set the license wait flag in the global environment
Implements
     BaseModel
ret = Model.acceptedSolutionStatus(what)
     This sets or gets the flag that indicated what solutions are accepted as expected when fetching
     primal and dual solution values.
     When fetching a solution value the status of the solution is checked against the flag.
     it matches, the solution is returned, otherwise an exception is thrown. The two methods
     Model.getPrimalSolutionStatus and Model.getDualSolutionStatus can be used to get the
     actual status of the solutions.
     By default the accepted solution status is NearOptimal.
Parameters
         •what (AccSolutionStatus) - The new accepted solution status.
Return
         •ret (void)
ret = Model.addConstraint(name, v)
     Add a set of constraints to one that is already in the model.
Parameters
         •name (string) - The name of the constraint set in the model
         •v (ModelConstraint) - The new contraint set
```

```
Return
        •ret (void)
ret = Model.addVariable(name, v)
     Add a set of variable to one that is already in the model.
Parameters
        •name (string) - The name of the variable set in the model
        •v (ModelVariable) - The new variable set
Return
        •ret (void)
ret = Model.breakSolver()
     Request that the solver terminates as soon as possible.
Return
        •ret (void)
ret = Model.clone()
     Clone the model.
Return
        •ret (Model)
ret = Model.constraint(name, expr, dom)
ret = Model.constraint(expr, dom)
ret = Model.constraint(name, expr, dom2)
ret = Model.constraint(expr, dom2)
ret = Model.constraint(name, shape, expr, dom3)
ret = Model.constraint(shape, expr, dom3)
ret = Model.constraint(name, expr, dom3)
ret = Model.constraint(expr, dom3)
ret = Model.constraint(name, shape, expr, dom4)
ret = Model.constraint(shape, expr, dom4)
ret = Model.constraint(name, expr, dom4)
ret = Model.constraint(expr, dom4)
ret = Model.constraint(name, shape, expr, dom5)
ret = Model.constraint(shape, expr, dom5)
ret = Model.constraint(name, expr, dom5)
ret = Model.constraint(expr, dom5)
ret = Model.constraint(name, v, dom)
ret = Model.constraint(v, dom)
ret = Model.constraint(name, v, dom2)
ret = Model.constraint(v, dom2)
ret = Model.constraint(name, shape, v, dom3)
ret = Model.constraint(shape, v, dom3)
ret = Model.constraint(name, v, dom3)
ret = Model.constraint(v, dom3)
ret = Model.constraint(name, shape, v, dom4)
ret = Model.constraint(shape, v, dom4)
ret = Model.constraint(name, v, dom4)
ret = Model.constraint(v, dom4)
ret = Model.constraint(name, shape, v, dom5)
ret = Model.constraint(shape, v, dom5)
ret = Model.constraint(name, v, dom5)
ret = Model.constraint(v, dom5)
Parameters
```

•name (string) – Name of the constraint. This must be unique among all constraints in the model. The value NULL is allowed instead of a unique name.

```
•expr (Expression) - An expression.
         •dom (PSDDomain) - Defines the domain of the expression. The shape and size of the domain
          must match the shape og the expression.
         •dom2 (LinPSDDomain) - Defines the domain of the expression. The shape and size of the
          domain must match the shape og the expression.
         •dom4 (RangeDomain) - Defines the domain of the expression. The shape and size of the
          domain must match the shape og the expression.
         •dom5 (QConeDomain) - Defines the domain of the expression. The shape and size of the
          domain must match the shape og the expression.
         • shape (Set) - Defines the shape of the constraint. If this is NULL, the shape will be derived
          from the shape of expr.
         •v (Variable) - A variable used as an expression.
         •dom3 (LinearDomain) - Defines the domain of the expression. The shape and size of the
          domain must match the shape og the expression.
         •ret (Constraint)
ret = Model.dispose()
     Destroy the Model object
         •ret (void)
ret = Model.dualObjValue()
     Get the dual objective value.
         •ret (double)
ret = Model.flushSolutions()
     If any solution values have been inputted, flush those values to the underlying task.
         •ret (void)
ret = Model.getAcceptedSolutionStatus()
     Get the the accepted solution status.
         •ret (AccSolutionStatus)
{\tt ret} = {\tt Model.getConstraint(name)}
ret = Model.getConstraint(index)
     Get the constraint corresponding to the given name or index
Parameters
         •name (string) - The constraint name
         •index (int32) - The constraint index
         •ret (Constraint)
ret = Model.getDualSolutionStatus(which)
ret2 = Model.getDualSolutionStatus()
Parameters
         •which (SolutionType) - the type of the solution (see SolutionType)
```

Return

Return

Return

Return

Return

Return

Return

13.1. Class list 171

•ret (SolutionStatus) - The dual solution SolutionStatus

```
•ret2 (SolutionStatus)
ret = Model.getName()
     Return the model name, or an empty string if it has not been set.
Return
        •ret (string) - The model name.
ret = Model.getPrimalSolutionStatus(which)
ret2 = Model.getPrimalSolutionStatus()
Parameters
        •which (SolutionType) - the type of the solution (see SolutionType)
Return
        •ret (SolutionStatus) - The primal solution SolutionStatus
        •ret2 (SolutionStatus)
ret = Model.getProblemStatus(which)
     Return the problem status
Parameters
        •which (SolutionType) - the type of the solution (see SolutionType)
Return
        •ret (ProblemStatus) - The problem status ProblemStatus
ret = Model.getSolverDoubleInfo(name)
     Fetch a solution information item from the solver
Parameters
        •name (string) - A string identifying the information to be fetched.
Return
        •ret (double)
ret = Model.getSolverIntInfo(name)
     Fetch a solution information item from the solver
Parameters
        •name (string)
Return
        •ret (int32)
ret = Model.getSolverLIntInfo(name)
     Fetch a solution information item from the solver
Parameters
        •name (string)
Return
        •ret (int64)
ret = Model.getTask()
     Return the underlying MOSEK task object.
Return
        •ret (Task)
ret = Model.getVariable(name)
ret = Model.getVariable(index)
     Get the variable corresponding to the given name or index
Parameters
        •name (string) - The variable name
        •index (int32) - The variable index
Return
```

```
●ret (Variable)
ret = Model.hasConstraint(name)
     Return whether the model contains a constraint with a given name.
Parameters
         •name (string) - The constraint name
Return
         •ret (bool)
ret = Model.hasVariable(name)
     Return whether the model contains a variable with a given name.
Parameters
         •name (string) - The variable name
Return
         •ret (bool)
ret = Model.numConstraints()
     Return the number of constraints
Return
         •ret (int64)
ret = Model.numVariables()
     Return the number of variables
Return
         •ret (int64)
ret = Model.objective(name, sense, expr)
ret = Model.objective(name, sense, v)
ret = Model.objective(name, sense, c)
ret = Model.objective(name, c)
ret = Model.objective(sense, expr)
ret = Model.objective(sense, v)
ret = Model.objective(sense, c)
ret = Model.objective(c)
     Replace the objective expression.
Parameters
         •name (string) - Name of the obective; this may be any string, and its has no function except
          when writing the problem to an external file formal.
         •sense (ObjectiveSense) - The objective sense; defines whether the objective must be mini-
          mized or maximized.
         •expr (Expression) - The objective expression. This must be an expression containing exactly
          one row.
         •v (Variable) - The objective variable. This must be a scaler variable.
         •c (double)
Return
         •ret (void)
ret = Model.primalObjValue()
     Get the primal objective value.
Return
         •ret (double)
ret = Model.putlicensecode(code)
     Set the license code in the global environment
Parameters
```

```
•code (int32[])
Return
         •ret (void)
ret = Model.putlicensepath(licfile)
     Set the license path in the global environment
Parameters
         •licfile (string)
Return
         •ret (void)
ret = Model.putlicensewait(wait)
     Set the license wait flag in the global environment
Parameters
         •wait (bool)
Return
         •ret (void)
ret = Model.selectedSolution(soltype)
     Set which solution to take values from.
Parameters
         •soltype (SolutionType)
Return
         •ret (void)
ret = Model.setCallbackHandler(h)
     Attach a callback handler.
Parameters
         •h (System.CallbackHandler) - The callback handler or NULL.
Return
         •ret (void)
ret = Model.setLogHandler(h)
     Attach a log handler.
Parameters
         •h (System.StreamWriter) - The log handler object or NULL.
Return
         •ret (void)
ret = Model.setSolverParam(name, strval)
ret = Model.setSolverParam(name, intval)
ret = Model.setSolverParam(name, floatval)
     Solver parameter values can be either symbolic values, integers or doubles, depending on the
     parameter. The value is automatically converted to a suitable type, or, if this fails, an exception
     will be thrown. For example, if the parameter accepts a double value and is give a string, the string
     will be parsed to produce a double.
     See 13.4.1 for a listing of all parameter settings.
Parameters
         •name (string) - Name of the parameter to set
         •strval (string) – A string value to assign to the parameter.
         •intval (int32) – An integer value to assign to the parameter.
         •floatval (double) - A float value to assign to the parameter.
Return
```

```
•ret (void)
ret = Model.solve()
     Attempt to optimize the model.
Return
        •ret (void)
ret = Model.variable(name)
ret = Model.variable(name, size)
ret = Model.variable(name, size2)
ret = Model.variable(name, size, dom)
ret = Model.variable(name, size, dom2)
ret = Model.variable(name, size, dom3)
ret = Model.variable(name, shp, dom)
ret = Model.variable(name, shp, dom2)
ret = Model.variable(name, shp, dom3)
ret = Model.variable(name, size2, dom)
ret = Model.variable(name, size2, dom2)
ret = Model.variable(name, dom)
ret = Model.variable(name, dom2)
ret = Model.variable(name, dom3)
ret = Model.variable()
ret = Model.variable(size)
ret = Model.variable(size2)
ret = Model.variable(size, dom)
ret = Model.variable(size, dom2)
ret = Model.variable(size, dom3)
ret = Model.variable(shp, dom)
ret = Model.variable(shp, dom2)
ret = Model.variable(shp, dom3)
ret = Model.variable(size2, dom)
ret = Model.variable(size2, dom2)
ret = Model.variable(dom)
ret = Model.variable(dom2)
ret = Model.variable(dom3)
ret2 = Model.variable(name, size, dom4)
ret2 = Model.variable(size, dom4)
ret = Model.variable(name, shp, dom5)
ret = Model.variable(name, n, dom5)
ret = Model.variable(name, n, m, dom5)
ret = Model.variable(name, dom5)
ret = Model.variable(n, dom5)
ret = Model.variable(n, m, dom5)
ret = Model.variable(dom5)
ret = Model.variable(name, shp, dom6)
ret = Model.variable(name, n, dom6)
ret = Model.variable(name, n, m, dom6)
ret = Model.variable(name, dom6)
ret = Model.variable(n, dom6)
ret = Model.variable(n, m, dom6)
ret = Model.variable(dom6)
```

The shape and the domain of the variable must match.

There are a long list of overloaded methods for variable creation, but they are all variations over the same method:

```
variable(name, shp, dom)
```

where any or all of name and shp can be left out, and dom can be either a Domain or a RangeDomain.

Parameters

- •name (string) Name of the variable. This must be unique among all variables in the model. The value NULL is allowed instead of a unique name.
- •size (int32) Size of the variable. The variable becomes a one-dimensional vector of the given size.
- •dom (*LinearDomain*) Defines the domain of the variable. The shape and the domain must match: The domain must either be scalable, e.g. *Domain.equalsTo* (0.0), or the size and shape must be matched by the shape defined by either shape or size.
- •dom4 (SymmetricLinearDomain) Defines the domain of the variable. The shape and the domain must match: The domain must either be scalable, e.g. Domain.equalsTo (0.0), or the size and shape must be matched by the shape defined by either shape or size.
- \bullet shp (Set) Defines the shape of the variable.
- •size2 (int32[]) Size of the variable. The variable becomes a one-dimensional vector of the given size.
- •dom2 (RangeDomain) Defines the domain of the variable. The shape and the domain must match: The domain must either be scalable, e.g. Domain.equalsTo(0.0), or the size and shape must be matched by the shape defined by either shape or size.
- •dom3 (*QConeDomain*) Defines the domain of the variable. The shape and the domain must match: The domain must either be scalable, e.g. *Domain.equalsTo* (0.0), or the size and shape must be matched by the shape defined by either shape or size.
- •dom5 (*PSDDomain*) Defines the domain of the variable. The shape and the domain must match: The domain must either be scalable, e.g. *Domain.equalsTo* (0.0), or the size and shape must be matched by the shape defined by either shape or size.
- •n (int32)
- •m (int32)
- •dom6 (LinPSDDomain) Defines the domain of the variable. The shape and the domain must match: The domain must either be scalable, e.g. Domain.equalsTo (0.0), or the size and shape must be matched by the shape defined by either shape or size.

Return

```
•ret (Variable)
```

•ret2 (SymmetricVariable)

ret = Model.writeTask(filename)

Dump the current solver task to a file.

Parameters

•filename (string) - Name of the file to write.

Return

•ret (void)

13.1.22 Class ModelConstraint

mosek.fusion.ModelConstraint

Base class for all constraints that directly corresponds to a block of constraints in the underlying task, i.e. all objects created from Model.constraint.

Members

```
Constraint. add - Add an expression to the constraint expression.
```

Constraint.dual

 ${\it Constraint.get_model}$ — Get the original model object.

```
Constraint. get_nd - Get the number of dimensions of the constraint.
     Constraint. index - Get a single element from a one-dimensional constraint.
     Constraint. level - Get the primal solution value of the variable.
     Constraint.shape
     Constraint. size - Get the total number of elements in the constraint.
     ModelConstraint.slice
     ModelConstraint.toString - Create a human readable representation of the constraint.
Implements
     Constraint
Implemented by
     ConicConstraint, RangedConstraint, LinearConstraint, PSDConstraint,
     Linear PSD Constraint
ret = ModelConstraint.slice(first, last)
ret = ModelConstraint.slice(first2, last2)
Parameters
         •first (int32) - Index of the first element in the slice.
         •last (int32) - Index if the last element in the slice.
         •first2 (int32[]) - Array of start elements in the slice.
         •last2 (int32[]) - Array of end element in the slice.
Return
         •ret (Constraint)
ret = ModelConstraint.toString()
     Create a human readable representation of the constraint.
Return
         •ret (string)
```

13.1.23 Class ModelVariable

mosek.fusion.ModelVariable

Base class for all variables that directly corresponds to a block of variables in the underlying task, i.e. all objects created from <code>Model.variable</code>.

```
BaseVariable.antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr - Create an expression corresponding to the variable object.

BaseVariable.diag - Return the diagonal of a square variable matrix.

BaseVariable.dual - Get the dual solution value of the variable.

BaseVariable.getModel - Return the model to which the variable belongs

BaseVariable.getShape - Return the model to which the variable belongs

BaseVariable.index - Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level - Get the primal solution value of the variable.

BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any

BaseVariable.makeInteger - Apply integrality constraints on the variable
```

13.1. Class list 177

Base Variable. pick - Create a slice variable by picking a list of indexes from this variable.

```
BaseVariable.setLevel - Input solution values for this variable
     BaseVariable. shape - Return the shape of the variable.
     BaseVariable.size - Get the number of elements in the variable.
     BaseVariable. toString - Create a string-representation of the variable.
     BaseVariable. transpose - Transpose a vector or matrix variable
     ModelVariable.slice - Create a slice variable by picking a range of indexes for each variable
     dimension
Implements
     BaseVariable
Implemented by
     Conic Variable, Linear PSD Variable, Ranged Variable, Linear Variable, PSD Variable,
     SymLinearVariable, SymRangedVariable
ret = ModelVariable.slice(first, last)
ret = ModelVariable.slice(first2, last2)
     Create a slice variable by picking a range of indexes for each variable dimension
Parameters
         •first (int32) - The index of the first element(s) of the slice.
         •last (int32) – The index of the first element after the end of the slice.
         •first2 (int32[]) - The index of the first element(s) of the slice.
         •last2(int32[])
Return
         •ret (Variable)
13.1.24 Class NDSparseArray
mosek.fusion.NDSparseArray
     Representation of a sparse n-dimensional array
     Static Members NDSparseArray.make Create a sparse n-dimensional matrix (tensor)
ret = NDSparseArray.make(dims, sub, cof)
ret = NDSparseArray.make(dims, inst, cof)
\mathtt{ret} = \mathtt{NDSparseArray.make(m)}
     Create a sparse n-dimensional matrix (tensor)
Parameters
         •dims (int32[]) - Array dimensions
         •sub (int32[][]) - Array of non-zero n-dimensional subscripts
         •cof (double[]) - Array of coefficients corresponding to subscripts
         •inst (int64[]) - Array of linear indexes of non-zero subscripts
         •m (Matrix)
Return
         •ret (NDSparseArray)
13.1.25 Class PSDConstraint
```

mosek.fusion.PSDConstraint

This class represents a semidefinite conic constraint of the form

$$Ax - b \succeq 0$$

```
i.e. Ax - b must be positive semidefinite
     Members
     Constraint. add - Add an expression to the constraint expression.
     Constraint.dual
     Constraint.get_model - Get the original model object.
     Constraint.get_nd - Get the number of dimensions of the constraint.
     Constraint. index - Get a single element from a one-dimensional constraint.
     Constraint. level - Get the primal solution value of the variable.
     Constraint.shape
     Constraint.size - Get the total number of elements in the constraint.
     ModelConstraint.slice
     PSDConstraint.toString - Create a human readable representation of the constraint.
Implements
     ModelConstraint
ret = PSDConstraint.toString()
     Create a human readable representation of the constraint.
Return
```

13.1.26 Class PSDDomain

•ret (string)

mosek.fusion.PSDDomain

Represent the domain od PSD matrices.

13.1.27 Class PSDVariable

```
mosek.fusion.PSDVariable
```

This class represents a positive semidefinite variable.

```
Members

BaseVariable.antidiag — Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr — Create an expression corresponding to the variable object.

BaseVariable.diag — Return the diagonal of a square variable matrix.

BaseVariable.dual — Get the dual solution value of the variable.

BaseVariable.getModel — Return the model to which the variable belongs

BaseVariable.getShape — Return the model to which the variable belongs

BaseVariable.index — Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level — Get the primal solution value of the variable.

BaseVariable.makeContinuous — Drop integrality constraints on the variable, if any

BaseVariable.makeInteger — Apply integrality constraints on the variable.

BaseVariable.pick — Create a slice variable by picking a list of indexes from this variable.
```

13.1. Class list 179

BaseVariable.setLevel - Input solution values for this variable

BaseVariable. shape - Return the shape of the variable.

```
BaseVariable.size - Get the number of elements in the variable.
     BaseVariable.transpose - Transpose a vector or matrix variable
     ModelVariable.slice - Create a slice variable by picking a range of indexes for each variable
     dimension
     PSDVariable.toString – Create a string-representation of the variable.
Implements
     ModelVariable
ret = PSDVariable.toString()
     Create a string-representation of the variable.
Return
         •ret (string)
13.1.28 Class PickVariable
mosek.fusion.PickVariable
     Represents an set of variable entries
     Members
     BaseVariable.antidiag - Return the antidiagonal of a square variable matrix.
     BaseVariable.asExpr - Create an expression corresponding to the variable object.
     BaseVariable. diag - Return the diagonal of a square variable matrix.
     BaseVariable.dual - Get the dual solution value of the variable.
     BaseVariable.getModel - Return the model to which the variable belongs
     BaseVariable. getShape - Return the model to which the variable belongs
     BaseVariable.index - Return a variable slice of size 1 corresponding to a single element in the
     variable object..
     BaseVariable. level - Get the primal solution value of the variable.
     BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any
     BaseVariable.makeInteger - Apply integrality constraints on the variable
     BaseVariable.pick - Create a slice variable by picking a list of indexes from this variable.
     BaseVariable.setLevel - Input solution values for this variable
     BaseVariable. shape - Return the shape of the variable.
     BaseVariable.size - Get the number of elements in the variable.
     BaseVariable. toString - Create a string-representation of the variable.
     BaseVariable.transpose - Transpose a vector or matrix variable
     PickVariable.slice - Create a slice variable by picking a range of indexes for each variable
     dimension
Implements
     BaseVariable
ret = PickVariable.slice(first, last)
ret = PickVariable.slice(first2, last2)
     Create a slice variable by picking a range of indexes for each variable dimension
Parameters
         •first (int32) - The index of the first element(s) of the slice.
```

•last (int32) – The index of the first element after the end of the slice.

```
•first2 (int32[]) - The index of the first element(s) of the slice.
        •last2 (int32[])
Return
        •ret (Variable)
13.1.29 Class ProductSet
mosek.fusion.ProductSet
     One-dimensional set defined as a range of integers.
     Members ProductSet.indexToString
ret = ProductSet.indexToString(index)
Parameters
        •index (int64)
Return
        •ret (string)
13.1.30 Class QConeDomain
mosek.fusion.QConeDomain
     A domain representing the Lorentz cone.
     Members
     QConeDomain.axis - Set the dimension along which the cones are created.
     QConeDomain.getAxis - Get the dimension along which the cones are created.
     QConeDomain.integral - Creates a domain of integral variables.
ret = QConeDomain.axis(a)
     Set the dimension along which the cones are created.
Parameters
        •a (int32)
Return
        ◆ret (QConeDomain)
ret = QConeDomain.getAxis()
     Get the dimension along which the cones are created.
Return
        •ret (int32)
ret = QConeDomain.integral()
     Creates a domain of integral variables.
Return
        •ret (QConeDomain)
13.1.31 Class RangeDomain
```

mosek.fusion.RangeDomain

The RangeDomain object is never instantiated directly: Instead use the relevant methods in Domain.

Members

RangeDomain.integral - Creates a domain of integral variables.

```
RangeDomain. sparse - Creates a domain exploiting sparsity.
     RangeDomain. symmetric - Creates a symmetric domain.
Implemented by
     SymmetricRangeDomain
ret = RangeDomain.integral()
     Creates a domain of integral variables.
Return
        ●ret (RangeDomain)
ret = RangeDomain.sparse()
     Creates a domain exploiting sparsity.
Return
        •ret (RangeDomain)
ret = RangeDomain.symmetric()
     Creates a symmetric domain.
Return
        •ret (SymmetricRangeDomain) - A new domain
```

13.1.32 Class RangedConstraint

${\tt mosek.fusion.RangedConstraint}$

Defines a ranged constraint.

Since this actually defines one constraint with two inequalities, there will be two dual values (slc and suc) corresponding to the lower and upper bounds. When asked for the dual solution, this constraint will return (y=slc-suc), but in some cases this is not enough (the individual dual constraints may be required for a certificate of infeasibility). The methods <code>RangedConstraint.lowerBoundCon</code> and <code>RangedConstraint.upperBoundCon</code> returns Variable objects that interface to the lower and upper bounds respectively.

Members

```
Constraint.add - Add an expression to the constraint expression.

Constraint.dual

Constraint.get_model - Get the original model object.

Constraint.get_nd - Get the number of dimensions of the constraint.

Constraint.index - Get a single element from a one-dimensional constraint.

Constraint.level - Get the primal solution value of the variable.

Constraint.shape

Constraint.size - Get the total number of elements in the constraint.

ModelConstraint.slice

ModelConstraint.toString - Create a human readable representation of the constraint.

RangedConstraint.lowerBoundCon - Get a constraint object corresponding to the lower bound of the ranged constraint.upperBoundCon - Get a constraint object corresponding to the upper bound
```

Implements

ModelConstraint

of the ranged constraint.

```
ret = RangedConstraint.lowerBoundCon()
```

Get a constraint object corresponding to the lower bound of the ranged constraint.

Return

•ret (Constraint) - A new constraint object representing the lower bound of the constraint.

ret = RangedConstraint.upperBoundCon()

Get a constraint object corresponding to the upper bound of the ranged constraint. Return

•ret (Constraint) - A new constraint object representing the upper bound of the constraint.

13.1.33 Class RangedVariable

mosek.fusion.RangedVariable

Defines a ranged variable.

Since this actually defines one variable with two inequalities, there will be two dual variables (slx and sux) corresponding to the lower and upper bounds. When asked for the dual solution, this variable will return (y=slx-sux), but in some cases this is not enough (the individual dual variables may be required by e.g. a certificate). The methods RangedVariable.lowerBoundVar and RangedVariable.upperBoundVar returns Variable objects that interface to the lower and upper bounds respectively.

Members

BaseVariable.antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr - Create an expression corresponding to the variable object.

BaseVariable.diag - Return the diagonal of a square variable matrix.

BaseVariable.dual - Get the dual solution value of the variable.

BaseVariable.getModel - Return the model to which the variable belongs

BaseVariable.getShape - Return the model to which the variable belongs

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable. level - Get the primal solution value of the variable.

BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any

BaseVariable.makeInteger - Apply integrality constraints on the variable

BaseVariable.pick - Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel - Input solution values for this variable

 ${\it BaseVariable.shape}$ — Return the shape of the variable.

BaseVariable.size - Get the number of elements in the variable.

 ${\it BaseVariable.}\ to {\it String}- {\it Create a string-representation of the variable}.$

BaseVariable. transpose - Transpose a vector or matrix variable

 ${\it ModelVariable.slice}$ — Create a slice variable by picking a range of indexes for each variable dimension

 $RangedVariable.\ lowerBoundVar$ — Get a variable object corresponding to the lower bound of the ranged variable.

 ${\it RangedVariable.upperBoundVar}$ – Get a variable object corresponding to the upper bound of the ranged variable.

Implements

ModelVariable

ret = RangedVariable.lowerBoundVar()

Get a variable object corresponding to the lower bound of the ranged variable.

```
Return
```

```
•ret (Variable) - A variable object representing the lower bound of the variable.
ret = RangedVariable.upperBoundVar()
     Get a variable object corresponding to the upper bound of the ranged variable.
Return
         •ret (Variable) - A variable object representing the upper bound of the variable.
13.1.34 Class Set
mosek.fusion.Set
     Base class shape specification objects.
     Set. compare - Compare two sets and return true if they have the same shape and size.
     Set. dim - Return the size of the given dimension.
     Set.getSize - Total number of elements in the set.
     Set. getname - Return a string representing the index.
     Set. idxtokey - Convert a linear index to a N-dimensional key.
     Set. realnd - Number of dimensions of more than 1 element, or 1 if the number of significant
     dimensions is 0.
     Set.slice - Create a set object representing a slice of this set.
     Set. stride - Return the stride size in the given dimension.
     Set. toString - Return a string representation of the set.
     Static Members
     Set.make - Creates a set object
     Set.scalar - Create a set of size 1
Implemented by
     BaseSet
ret = Set.compare(other)
     Compare two sets and return true if they have the same shape and size.
Parameters
         •other (Set) - The set to compare against.
Return
         •ret (bool) – Whether the two set are equal.
ret = Set.dim(i)
     Return the size of the given dimension.
Parameters
         •i (int32) – Dimension index.
Return
         •ret (int32) - The size of the requested dimension.
ret = Set.getSize()
     Total number of elements in the set.
Return
```

•ret (int64) – The number of elements.

 $\mathtt{ret} = \mathtt{Set.getname(key)}$

184

```
ret = Set.getname(keya)
     Return a string representing the index.
Parameters
         •key (int64) - A linear index.
         •keya (int32[]) - An N-dimensional index.
Return
         •ret (string) - Get a string representing the item identified by the key.
ret = Set.idxtokey(idx)
     Convert a linear index to a N-dimensional key.
Parameters
         •idx (int64) - A linear index.
Return
         •ret (int32[]) - The N-dimensional key for the linear index.
ret = Set.make(names)
ret = Set.make(sz)
ret = Set.make(s1, s2)
ret = Set.make(s1, s2, s3)
\mathtt{ret} = \mathtt{Set.make}(\mathtt{sizes})
ret = Set.make(s12, s22)
ret = Set.make(ss)
     This static method is a factory for different kind of set objects:
         •A (multi-dimensional) set of integers.
         •A set whose elements are strings.
         •A set obtained as Cartesian product of sets given in a list.
Parameters
         •names (string[]) - A list of strings
         •sz (int32) - The dimension for a integer set
         •s1 (int32) - Size of the first dimension
         •s2 (int32) - Size of the second dimension
         •s3 (int32) - Size of the third dimension
         •sizes (int32[]) - The sizes of dimensions for a integer set
         •s12 (Set) – Size of the first dimension
         •s22 (Set) - Size of the second dimension
         •ss (Set) - A list of sets
Return
         •ret (Set)
ret = Set.realnd()
     Number of dimensions of more than 1 element, or 1 if the number of significant dimensions is 0.
Return
         •ret (int32) - The number of dimensions.
ret = Set.scalar()
     Create a set of size 1
Return
         •ret (Set) - The new set.
ret = Set.slice(first, last)
```

```
ret = Set.slice(firsta, lasta)
     Create a set object representing a slice of this set.
Parameters
         •first (int32) - First index in the range.
         •last (int32) - Last index in the range.
         •firsta (int32[]) – First index in each dimension in the range.
         •lasta (int32[]) – Last index in each dimension in the range.
Return
         •ret (Set) - A new Set object representing the slice.
ret = Set.stride(i)
     Return the stride size in the given dimension.
Parameters
         •i (int32) – Dimension index.
Return
         •ret (int64) – The stride size in the requested dimension.
ret = Set.toString()
     Return a string representation of the set.
Return
         •ret (string) – A string representation of the set.
13.1.35 Class SliceConstraint
mosek.fusion.SliceConstraint
     An alias for a subset of constraints from a single ModelConstraint.
     This class acts as a proxy for accessing a portion of a ModelConstraint. It is possible to access
     and modify the properties of the original variable using this alias. It does not access the Model
     directly, only through the original variable.
     Members
     Constraint. add – Add an expression to the constraint expression.
     Constraint.dual
     Constraint.get_model - Get the original model object.
     Constraint.get_nd - Get the number of dimensions of the constraint.
     Constraint.index - Get a single element from a one-dimensional constraint.
     Constraint. level - Get the primal solution value of the variable.
     Constraint.shape
     Constraint. toString - Create a human readable representation of the constraint.
     SliceConstraint.size - Get the total number of elements in the constraint.
     SliceConstraint.slice
Implements
```

Chapter 13. Fusion API Reference

Return

 ${\it Constraint}$ Implemented by

BoundInterfaceConstraint

Get the total number of elements in the constraint.

ret = SliceConstraint.size()

```
An alias for a subset of variables from a single Model Variable.
     This class acts as a proxy for accessing a portion of a ModelVariable. It is possible to access
     and modify the properties of the original variable using this alias, and the object can be used in
     expressions as any other Variable object.
     Members
     BaseVariable. antidiag - Return the antidiagonal of a square variable matrix.
     BaseVariable.asExpr - Create an expression corresponding to the variable object.
     BaseVariable.diag - Return the diagonal of a square variable matrix.
     BaseVariable.dual - Get the dual solution value of the variable.
     BaseVariable.getModel - Return the model to which the variable belongs
     BaseVariable. qetShape - Return the model to which the variable belongs
     BaseVariable.index - Return a variable slice of size 1 corresponding to a single element in the
     variable object..
     BaseVariable. level - Get the primal solution value of the variable.
     BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any
     BaseVariable.makeInteger - Apply integrality constraints on the variable
     Base Variable. pick - Create a slice variable by picking a list of indexes from this variable.
     BaseVariable.setLevel - Input solution values for this variable
     BaseVariable. shape - Return the shape of the variable.
     BaseVariable. size - Get the number of elements in the variable.
     BaseVariable. toString - Create a string-representation of the variable.
     BaseVariable.transpose - Transpose a vector or matrix variable
     Slice Variable. slice - Create a slice variable by picking a range of indexes for each variable
     dimension
Implements
     BaseVariable
Implemented by
     BoundInterfaceVariable
ret = SliceVariable.slice(firstidx, lastidx)
```

```
ret = SliceVariable.slice(firstidx2, lastidx2)
```

Create a slice variable by picking a range of indexes for each variable dimension Parameters

- •firstidx (int32)
- •lastidx (int32)
- •firstidx2 (int32[])
- •lastidx2 (int32[])

Return

●ret (Variable)

13.1.37 Class SymLinearVariable

mosek.fusion.SymLinearVariable

A linear variable defines a block of variables with the same linear domain. The domain is either a product of product of one-dimensional half-spaces (linear inequalities), a fixed value vector (equalities) or the whole space (free variables).

The type of a linear variable is immutable; it is either free, an inequality or an equality.

The class is not meant to be instantiated directly, but must be created by calling the <code>Model.variable</code> method.

Members

BaseVariable.antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable. asExpr - Create an expression corresponding to the variable object.

BaseVariable.diag - Return the diagonal of a square variable matrix.

BaseVariable.dual - Get the dual solution value of the variable.

BaseVariable.getModel - Return the model to which the variable belongs

BaseVariable.getShape - Return the model to which the variable belongs

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable. level - Get the primal solution value of the variable.

BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any

BaseVariable.makeInteger - Apply integrality constraints on the variable

BaseVariable.pick - Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel - Input solution values for this variable

BaseVariable. shape - Return the shape of the variable.

BaseVariable.size - Get the number of elements in the variable.

BaseVariable. transpose - Transpose a vector or matrix variable

 ${\it ModelVariable.slice}$ — Create a slice variable by picking a range of indexes for each variable dimension

SymLinearVariable. toString - Create a string-representation of the variable.

Implements

ModelVariable

ret = SymLinearVariable.toString()

Create a string-representation of the variable.

Return

•ret (string)

13.1.38 Class SymRangedVariable

```
mosek.fusion.SymRangedVariable
```

Defines a ranged variable.

Since this actually defines one variable with two inequalities, there will be two dual variables (slx and sux) corresponding to the lower and upper bounds. When asked for the dual solution, this variable will return (y=slx-sux), but in some cases this is not enough (the individual dual variables may be required by e.g. a certificate). The methods RangedVariable.lowerBoundVar and RangedVariable.upperBoundVar returns Variable objects that interface to the lower and upper bounds respectively.

Members

BaseVariable. antidiag - Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr - Create an expression corresponding to the variable object.

BaseVariable.diag - Return the diagonal of a square variable matrix.

BaseVariable. dual - Get the dual solution value of the variable.

BaseVariable.getModel - Return the model to which the variable belongs

BaseVariable.getShape - Return the model to which the variable belongs

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable. level - Get the primal solution value of the variable.

BaseVariable.makeContinuous - Drop integrality constraints on the variable, if any

 ${\it BaseVariable.makeInteger}$ - Apply integrality constraints on the variable

BaseVariable.pick - Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel - Input solution values for this variable

BaseVariable. shape - Return the shape of the variable.

BaseVariable.size - Get the number of elements in the variable.

BaseVariable. transpose - Transpose a vector or matrix variable

ModelVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

SymRangedVariable. toString - Create a string-representation of the variable.

Implements

ModelVariable

ret = SymRangedVariable.toString()

Create a string-representation of the variable.

Return

•ret (string)

13.1.39 Class SymmetricExpr

mosek.fusion.SymmetricExpr

A guaranteed symmetric square matrix expression.

It is defined as

$$\sum_{i} (M_i x_i) + b,$$

 $where: math: `M_i`isa: msk: func: `Symmetric Matrix` and: math: `x_i`is a scalar variable. The properties of the prope$

Members SymmetricExpr. toString Returns a human readable representation of the expression.

ret = SymmetricExpr.toString()

Returns a human readable representation of the expression.

Return

•ret (string) - A string representing the expression.

13.1.40 Class SymmetricLinearDomain

mosek.fusion.SymmetricLinearDomain

Represent a linear domain with symmetry.

Members

SymmetricLinearDomain.integral - Creates a domain of integral variables.

SymmetricLinearDomain.sparse - Creates a domain exploiting sparsity.

ret = SymmetricLinearDomain.integral()

Creates a domain of integral variables.

Return

•ret (SymmetricLinearDomain)

ret = SymmetricLinearDomain.sparse()

Creates a domain exploiting sparsity.

Return

•ret (SymmetricLinearDomain)

13.1.41 Class SymmetricRangeDomain

mosek.fusion.SymmetricRangeDomain

Represent a ranged domain with symmetry.

Members

RangeDomain.integral - Creates a domain of integral variables.

RangeDomain.sparse - Creates a domain exploiting sparsity.

RangeDomain. symmetric - Creates a symmetric domain.

Implements

RangeDomain

13.1.42 Class Symmetric Variable

mosek.fusion.SymmetricVariable

An object representing a symmetric variable.

Members

190

Variable. antidiag - Return the antidiagonal of a square variable matrix.

Variable.asExpr - Create an expression corresponding to the variable object.

Variable.diag - Return the diagonal of a square variable matrix.

```
Variable. dual - Return the dual value of the variable as an array.
     Variable. qetModel - Return the model to which the variable belongs
     Variable.getShape - Return the model to which the variable belongs
     Variable.index - Return a variable slice of size one corresponding to a single element in the
     variable object.
     Variable. level - Return the primal value of the variable as an array.
     Variable.makeContinuous - Drop integrality constraints on the variable, if any
     Variable.makeInteger - Apply integrality constraints on the variable
     Variable.pick - Create a slice variable by picking a list of indexes from this variable.
     Variable.setLevel - Input solution values for this variable
     Variable. shape - Return the shape of the variable.
     Variable. size - Get the number of elements in the variable.
     Variable. slice - Create a slice variable by picking a range of indexes for each variable dimension.
     Variable. toString - Create a string-representation of the variable.
     Variable. transpose - Transpose a vector or matrix variable
Implements
     Variable
Implemented by
     PSDVariable, SymLinearVariable, SymRangedVariable
13.1.43 Class Var
```

mosek.fusion.Var

Return

An abstract variable object. This is the base class for all variable types in Fusion, and it contains several static methods for manipulating variable objects.

The Variable object can be an interface to the normal model variables, e.g. LinearVariable and Conic Variable, to slices of other variables or to concatenations of other variables.

Primal and dual solution values can be accessed through the Variable object.

```
Static Members
     Var. compress - Reshape a variable object by removing all dimensions of size 1.
     Var. flatten - Create a one-dimensional logical view of a variable object.
     Var. hrepeat - Create a variable by repeating a variable in the second dimension.
     Var. hstack - Create a stacked variable in second dimension.
     Var. repeat - Create a variable by repeating a variable in a given dimension.
     Var. reshape - Create a reshaped version of the given variable.
     Var. stack - Create a stacked variable in dimension dim.
     Var. vrepeat - Create a variable by repeating a variable in a first dimension.
     Var. vstack - Create a stacked variable in first dimension.
ret = Var.compress(v)
     Reshape a variable object by removing all dimensions of size 1.
Parameters
```

•v (Variable) - The variable object to reshape.

```
●ret (Variable)
ret = Var.flatten(v)
      Create a one-dimensional logical view of a variable object.
Parameters
         •v (Variable) - The variable to be flattened
Return
         •ret (Variable) - A one-dimensional Variable object.
ret = Var.hrepeat(v, n)
      Create a variable by repeating a variable in the second dimension.
Parameters
         •v (Variable) - A variable object.
         •n (int32) - Number of times to repeat v.
Return
         ●ret (Variable)
ret = Var.hstack(v)
ret = Var.hstack(v1, v2)
ret = Var.hstack(v1, v2, v3)
      Create a stacked variable in second dimension.
Parameters
         •v (Variable) - List of variable to stack.
         •v1 (Variable) - The first variable in the stack.
         •v2 (Variable) - The second variable in the stack.
         \bullet v3 \; (\textit{Variable}) - \text{The third variable in the stack}.
Return
         •ret (Variable) - An object representing the concatenation of the variables.
ret = Var.repeat(v, dim, n)
ret = Var.repeat(v, n)
      Create a variable by repeating a variable in the given dimension. For an m-dimensional variable
      with the shape (d_1,\ldots,d_m): If the dimension, dim is negative, a new first dimension is inserted
     of size n, and the result will have shape (n, d_1, \ldots, d_m). Otherwise the result will have shape
      (d_1,\ldots,d_{\mathtt{dim}},\ldots,d_m).
     By default it will repeat in the first dimension.
Parameters
         •v (Variable) - A variable object.
         •dim (int32) - Dimension to repeat in. If this is negative, it means that the result adds a new
          dimension.
         •n (int32) – Number of times to repeat v.
Return
         ●ret (Variable)
ret = Var.reshape(v, s)
ret2 = Var.reshape(v2, dims)
\mathtt{ret2} = \mathtt{Var.reshape}(\mathtt{v2},\,\mathtt{d1},\,\mathtt{d2})
ret2 = Var.reshape(v2, d1)
      Create a reshaped version of the given variable.
Parameters
         •v (Variable) - The variable to be reshaped
         •s (Set) - The new shape of the variable
```

```
•v2 (Variable) - A variable object.
         •dims (int32[]) - An array containing the shape of the new variable.
         •d1 (int32) - Size of first dimension in the result.
         •d2 (int32) - Size of second dimension in the result.
Return
         •ret (Variable) - A new variable object with the shape defined by s
         •ret2 (Variable)
ret = Var.stack(v, dim)
ret = Var.stack(v1, v2, dim)
ret = Var.stack(v1, v2, v3, dim)
ret2 = Var.stack(vlist)
     Create a stacked variable in dimension dim.
Parameters
         •v (Variable) - List of variable to stack.
         •dim (int32) - Dimension in which to stack.
         •v1 (Variable) - First variable in the stack.
         •v2 (Variable) - Second variable in the stack.
         •v3 (Variable) - Third variable in the stack.
         •vlist (Variable) - The variables in the stack.
Return
         •ret (Variable)
         •ret2 (Variable) - An object representing the concatenation of the variables.
ret = Var.vrepeat(v, n)
     Create a variable by repeating a variable in the first dimension.
Parameters
         •v (Variable) - A variable object.
         •n (int32) - Number of times to repeat v.
Return
         ●ret (Variable)
ret = Var.vstack(v)
ret = Var.vstack(v1, v2)
ret = Var.vstack(v1, v2, v3)
     Create a stacked variable in first dimension.
Parameters
         •v (Variable) - List of variable to stack.
         •v1 (Variable) - First variable in the stack.
         •v2 (Variable) - Second variable in the stack.
         •v3 (Variable) - Third variable in the stack.
Return
         •ret (Variable) - An object representing the concatenation of the variables.
```

13.1.44 Class Variable

```
mosek.fusion.Variable
```

An abstract variable object. This is the base class for all variable types in Fusion, and it contains several static methods for manipulating variable objects.

The Variable object can be an interface to the normal model variables, e.g. LinearVariable and Conic Variable, to slices of other variables or to concatenations of other variables.

Primal and dual solution values can be accessed through the Variable object.

```
Members
```

```
Variable.antidiag - Return the antidiagonal of a square variable matrix.
```

Variable.asExpr - Create an expression corresponding to the variable object.

Variable. diag - Return the diagonal of a square variable matrix.

Variable.dual - Return the dual value of the variable as an array.

Variable.getModel - Return the model to which the variable belongs

Variable.getShape - Return the model to which the variable belongs

Variable.index – Return a variable slice of size one corresponding to a single element in the variable object.

Variable.level - Return the primal value of the variable as an array.

Variable.makeContinuous - Drop integrality constraints on the variable, if any

Variable.makeInteger - Apply integrality constraints on the variable

Variable.pick - Create a slice variable by picking a list of indexes from this variable.

Variable.setLevel - Input solution values for this variable

Variable. shape - Return the shape of the variable.

Variable. size - Get the number of elements in the variable.

Variable.slice - Create a slice variable by picking a range of indexes for each variable dimension.

Variable. toString - Create a string-representation of the variable.

Variable. transpose - Transpose a vector or matrix variable

Implemented by

```
BaseVariable, SymmetricVariable
```

```
ret = Variable.antidiag(index)
```

Return the antidiagonal of a square variable matrix.

Parameters

•index (int32) – Defining the index of the anti-diagonal. 0 is the diagonal starting at element (1,n). Positive values are the super-diagonals (diagonals in the upper triangular part, and negative are indexes of the sub-diagonals (in the lower triangular part).

Return

```
•ret (Variable)
```

```
ret = Variable.asExpr()
```

Create an expression corresponding to the variable object.

Return

•ret (Expression) – An Expression object representing the V variable.

```
ret = Variable.diag(index)
```

```
ret = Variable.diag()
```

Return the diagonal of a square variable matrix.

```
Parameters
```

•index (int32) – Defining the index of the diagonal. 0 is the diagonal starting at element (1,1). Positive values are the super-diagonals (diagonals in the upper triangular part, and negative are indexes of the sub-diagonals (in the lower triangular part).

Return

```
•ret (Variable)
```

 $\mathtt{ret} = \mathtt{Variable.dual}()$

Return the dual value of the variable as an array.

Return

•ret (double[]) - An array of solution values. When the selected slice is multi-dimensional, this corresponds to the flattened slice of solution values.

```
ret = Variable.getModel()
```

Return the model to which the variable belongs

Return

```
•ret (Model)
```

```
ret = Variable.getShape()
```

Return the model to which the variable belongs

Return

```
•ret (Set)
```

```
ret = Variable.index(i1)
ret = Variable.index(i1, i2)
```

ret = Variable.index(i1, i2, i3)

ret = Variable.index(idx)

Return a variable slice of size one corresponding to a single element in the variable object.

Parameters

- •i1 (int32) Index in the first dimension of the element requested.
- •i2 (int32) Index in the second dimension of the element requested.
- •i3 (int32) Index in the third dimension of the element requested.
- •idx (int32[]) List of indexes of the elements requested.

Return

```
•ret (Variable)
```

```
ret = Variable.level()
```

Return the primal value of the variable as an array.

Return

•ret (double[]) – An array of solution values. When the selected slice is multi-dimensional, this corresponds to the flattened slice of solution values.

```
ret = Variable.makeContinuous()
```

Drop integrality constraints on the variable, if any

Return

```
ulletret (void)
```

```
ret = Variable.makeInteger()
```

Apply integrality constraints on the variable

Return

```
•ret (void)
```

```
ret = Variable.pick(idxs)
ret = Variable.pick(midxs)
```

ret = Variable.pick(i1, i2)

```
ret = Variable.pick(i1, i2, i3)
     Create a slice variable by picking a list of indexes from this variable.
Parameters
         •idxs (int32[]) – Indexes of the elements requested.
         •midxs (int32[][]) - Matrix of indexes of the elements requested.
         •i1 (int32[]) – Index along the first dimension.
         •i2 (int32[]) - Index along the second dimension.
         \bullet {\tt i3} \ ({\tt int32[]}) - {\tt Index along the third dimension}.
Return
         •ret (Variable)
ret = Variable.setLevel(v)
     Input solution values for this variable
Parameters
         •v (double[]) - An array of values to be assigned to the variable.
Return
         •ret (void)
ret = Variable.shape()
     Return the shape of the variable.
Return
         •ret (Set) – A set representing the shape.
ret = Variable.size()
     Get the number of elements in the variable.
Return
         •ret (int64)
ret = Variable.slice(first, last)
ret = Variable.slice(firsta, lasta)
     Create a slice variable by picking a range of indexes for each variable dimension.
Parameters
         •first (int32) – The index of the first element of the slice.
         •last (int32) - The index of the first element after the end of the slice.
         •firsta (int32[]) - The indexes of the first elements of the slice along each dimension.
         •lasta (int32[]) - The indexes of the first elements after the end of the slice along each
          dimension.
Return
         •ret (Variable) - A new variable object representing a slice of this object.
ret = Variable.toString()
     Create a string-representation of the variable.
Return
         •ret (string) – A string representing the variable.
ret = Variable.transpose()
     Transpose a vector or matrix variable
Return
         •ret (Variable) - A new variable object.
```

13.2 Exceptions

- *DimensionError*: Thrown when a given object has the wrong number of dimensions, or they have not the right size.
- DomainError: Invalid domain.
- \bullet $\textit{ExpressionError}\colon \text{Tried}$ to construct an expression from invalid.
- FatalError: A fatal error has happened.
- FusionException: Base class for all normal exceptions in fusion.
- FusionRuntimeException: Base class for all run-time exceptions in fusion.
- *IOError*: Error when reading or writing a stream, or opening a file.
- IndexError: Index out of bound, or a multi-dimensional index had wrong number of dimensions.
- LengthError: None
- MatrixError: Thrown if data used in construction of a matrix contained inconsistencies or errors.
- ModelError: Thrown when objects from different models were mixed.
- NameError: Name clash; tries to add a variable or constraint with a name that already exists.
- OptimizeError: An error occurred during optimization.
- ParameterError: Tried to use an invalid parameter for a value that was invalid for a specific parameter.
- RangeError: Invalid range specified
- SetDefinitionError: Invalid data for constructing set.
- SliceError: Invalid slice definition, negative slice or slice index out of bounds.
- SolutionError: Requested a solution that was undefined or whose status was not acceptable.
- SparseFormatError: The given sparsity patters was invalid or specified an index that was out of bounds.
- UnexpectedError: An unexpected error has happened. No specific excepion could have been risen.
- UnimplementedError: Called a stub. Functionality has not yet been implemented.
- ValueConversionError: Error casting or converting a value.

13.2.1 Exception DimensionError

mosek.fusion.DimensionError

Thrown when a given object has the wrong number of dimensions, or they have not the right size.

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.2.2 Exception DomainError

mosek.fusion.DomainError

Invalid domain.

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.2. Exceptions 197

13.2.3 Exception ExpressionError

```
mosek.fusion.ExpressionError
```

Tried to construct an expression from invalid.

 ${\tt Members} \ \textit{FusionRuntimeException.toString} \ \text{Return the exception message}.$ ${\tt Implements}$

Fusion Runtime Exception

13.2.4 Exception FatalError

```
mosek.fusion.FatalError
```

A fatal error has happened.

Members RuntimeException.toString Return the exception message.

Implements

RuntimeException

13.2.5 Exception FusionException

```
{\tt mosek.fusion.FusionException}
```

Base class for all normal exceptions in fusion.

Members FusionException.toString Return the exception message.

Implements

Exception

Implemented by

 ${\it SolutionError}$

ret = FusionException.toString()

Return the exception message.

Return

•ret (string) - The message.

13.2.6 Exception FusionRuntimeException

```
mosek.fusion.FusionRuntimeException
```

Base class for all run-time exceptions in fusion.

Members FusionRuntimeException.toString Return the exception message.

Implements

RuntimeException

Implemented by

```
ValueConversionError, IndexError, ParameterError, SetDefinitionError, OptimizeError, NameError, IOError, RangeError, ModelError, DomainError, ExpressionError, LengthError, MatrixError, SparseFormatError, SliceError, DimensionError
```

ret = FusionRuntimeException.toString()

Return the exception message.

Return

•ret (string) - The message.

13.2.7 Exception IOError

mosek.fusion.IOError

Error when reading or writing a stream, or opening a file.

Members FusionRuntimeException.toString Return the exception message.

${\tt Implements}$

Fusion Runtime Exception

13.2.8 Exception IndexError

mosek.fusion.IndexError

Index out of bound, or a multi-dimensional index had wrong number of dimensions.

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.2.9 Exception LengthError

mosek.fusion.LengthError

An array did not have the required length, or two arrays were expected to have same length.

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.2.10 Exception MatrixError

mosek.fusion.MatrixError

Thrown if data used in construction of a matrix contained inconsistencies or errors.

Members FusionRuntimeException.toString Return the exception message.

Implements

 ${\it FusionRuntimeException}$

13.2.11 Exception ModelError

mosek.fusion.ModelError

Thrown when objects from different models were mixed.

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.2.12 Exception NameError

mosek.fusion.NameError

Name clash; tries to add a variable or constraint with a name that already exists.

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.2.13 Exception OptimizeError

mosek.fusion.OptimizeError

An error occurred during optimization.

Members FusionRuntimeException.toString Return the exception message.

13.2. Exceptions 199

Implements

 ${\it FusionRuntimeException}$

13.2.14 Exception ParameterError

mosek.fusion.ParameterError

Tried to use an invalid parameter for a value that was invalid for a specific parameter.

Members FusionRuntimeException.toString Return the exception message.

Implements

 ${\it Fusion Runtime Exception}$

13.2.15 Exception RangeError

mosek.fusion.RangeError

Invalid range specified

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.2.16 Exception SetDefinitionError

mosek.fusion.SetDefinitionError

Invalid data for constructing set.

Members FusionRuntimeException.toString Return the exception message.

Implements

 ${\it FusionRuntimeException}$

13.2.17 Exception SliceError

mosek.fusion.SliceError

Invalid slice definition, negative slice or slice index out of bounds.

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.2.18 Exception SolutionError

mosek.fusion.SolutionError

Requested a solution that was undefined or whose status was not acceptable.

Members FusionException. toString Return the exception message.

Implements

Fusion Exception

13.2.19 Exception SparseFormatError

mosek.fusion.SparseFormatError

The given sparsity patters was invalid or specified an index that was out of bounds.

 ${\tt Members}\ \textit{FusionRuntimeException.toString}\ \text{Return the exception message}.$

Implements

Fusion Runtime Exception

13.2.20 Exception UnexpectedError

mosek.fusion.UnexpectedError

An unexpected error has happened. No specific excepion could have been risen.

Members RuntimeException.toString Return the exception message.

Implements

RuntimeException

13.2.21 Exception UnimplementedError

mosek.fusion.UnimplementedError

Called a stub. Functionality has not yet been implemented.

Members RuntimeException.toString Return the exception message.

Implements

RuntimeException

13.2.22 Exception ValueConversionError

mosek.fusion.ValueConversionError

Error casting or converting a value.

Members FusionRuntimeException.toString Return the exception message.

Implements

Fusion Runtime Exception

13.3 Enumerations

AccSolutionStatus

Constants used for defining which solutions statuses are acceptable.

Anything

Accept all solution status except *Undefined*.

Optimal

Accept only optimal solution status.

${\tt NearOptimal}$

Accept only optimal solution status.

Feasible

Accept any feasible solution, even if not optimal.

Certificate

Accept only a certificate.

ObjectiveSense

Used in Model. objective to define the objective sense of the Model.

Undefined

The sense is not defined; trying to optimize a <code>Model</code> whose objective sense is undefined is an error.

Minimize

Minimize the objective.

Maximize

Maximize the objective.

13.3. Enumerations 201

PSDKey

IsSymPSD

IsTrilPSD

ProblemStatus

Constants used for defining which solutions statuses are acceptable.

Unknown

Unknown problem status.

PrimalAndDualFeasible

The problem is feasible.

PrimalFeasible

The problem is at least primal feasible.

DualFeasible

The problem is at least least dual feasible.

PrimalInfeasible

The problem is primal infeasible.

DualInfeasible

The problem is dual infeasible.

PrimalAndDualInfeasible

The problem is primal and dual infeasible.

IllPosed

The problem is illposed.

PrimalInfeasibleOrUnbounded

The problem is primal infeasible or unbounded.

QConeKey

InQCone

 ${\tt InRotatedQCone}$

RelationKey

Used internally in *Fusion* to define the domain type for a constraint or variable.

EqualsTo

LessThan

GreaterThan

IsFree

InRange

SolutionStatus

Defines properties of either a primal or a dual solution. A model may contain multiple solutions which may have different status.

Specifically, there will be individual solutions, and thus solution statuses, for the interior-point, simplex and integer solvers.

Undefined

Undefined solution. This means that no values exist for the relevant solution.

Unknown

The solution status is unknown; this will happen if the user inputs values or a solution is read from a file.

Optimal

The solution values are feasible and optimal.

NearOptimal

The solution values are feasible and nearly optimal.

Feasible

The solution is feasible.

NearFeasible

The solution is nearly feasible.

Certificate

The solution is a certificate of infeasibility (primal or dual, depending no which solution it belongs to).

NearCertificate

The solution is nearly a certificate of infeasibility (primal or dual, depending no which solution it belongs to).

IllposedCert

SolutionType

Used when requesting a specific solution from a Model.

Default

Auto-select the default solution; usually this will be the integer solution, if available, otherwise the basic solution, if available, otherwise the interior-point solution.

Basic

Select the basic solution.

Interior

Select the interior-point solution.

Integer

Select the integer solution.

StatusKey

Defines the status of a single solution value.

Unknown

The status is unknown; this will happen if, for example, the solution was read from a file or inputted by the user.

Basic

The solution is basic.

SuperBasic

The value is superbasic.

OnBound

The value is on its bound.

Infinity

The solution value is infinite, or sufficiently large to be deemed infinite.

13.4 Parameters

All parameters (alphabetical order)

Parameters grouped by topic

Note: some parameters may appear in more than one group.

13.4. Parameters 203

- Conic interior-point method
- Interior-point method
- Mixed-integer optimization
- Overall solver
- Solution input/output
- Termination criterion
- Analysis
- Optimization system
- Primal simplex optimizer
- Output information
- Basis identification
- Presolve
- Data input/output
- Infeasibility report
- Simplex optimizer
- Nonlinear convex method
- Dual simplex optimizer
- License manager
- Data check
- Logging

13.4.1 Parameters List (alphabetically)

Double Parameters

anaSolInfeasTol

If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer.

Accepted Values: $[0.0; +\inf]$

 ${\tt Default\ Value:} \quad 1e\text{-}6$

 ${\tt Groups:} \quad \textit{Analysis}$

basisRelTolS

Maximum relative dual bound violation allowed in an optimal basic solution.

Accepted Values: $[0.0;+\inf]$

 ${\tt Default\ Value:} \quad 1.0e\text{-}12$

Groups: Simplex optimizer, Termination criterion

basisTolS

Maximum absolute dual bound violation in an optimal basic solution.

Accepted Values: [1.0e-9;+inf]

Default Value: 1.0e-6

Groups: Simplex optimizer, Termination criterion

basisTolX

Maximum absolute primal bound violation allowed in an optimal basic solution.

Accepted Values: [1.0e-9;+inf]

Default Value: 1.0e-6

Groups: Simplex optimizer, Termination criterion

intpntCoTolDfeas

Dual feasibility tolerance used by the conic interior-point optimizer.

Accepted Values: [0.0;1.0]

Default Value: 1.0e-8

Groups: Interior-point method, Termination criterion, Conic interior-point method

$\verb|intpntCoTolInfeas|$

Controls when the conic interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Accepted Values: [0.0;1.0]

Default Value: 1.0e-10

Groups: Interior-point method, Termination criterion, Conic interior-point method

intpntCoTolMuRed

Relative complementarity gap feasibility tolerance used by the conic interior-point optimizer.

Accepted Values: [0.0;1.0]

Default Value: 1.0e-8

Groups: Interior-point method, Termination criterion, Conic interior-point method

$\verb|intpntCoTolNearRel|$

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Accepted Values: $[1.0; +\inf]$

Default Value: 1000

Groups: Interior-point method, Termination criterion, Conic interior-point method

intpntCoTolPfeas

Primal feasibility tolerance used by the conic interior-point optimizer.

Accepted Values: [0.0; 1.0]

Default Value: 1.0e-8

 ${\tt Groups:} \quad \textit{Interior-point method, Termination criterion, Conic interior-point method}$

$\verb"intpntCoTolRelGap"$

Relative gap termination tolerance used by the conic interior-point optimizer.

Accepted Values: [0.0;1.0]

Default Value: 1.0e-7

Groups: Interior-point method, Termination criterion, Conic interior-point method

intpntQoTolDfeas

Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem..

Accepted Values: [0.0;1.0]

Default Value: 1.0e-8

13.4. Parameters 205

Groups: Interior-point method, Termination criterion

intpntQoTolInfeas

Controls when the conic interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Accepted Values: [0.0;1.0]

Groups: Interior-point method, Termination criterion

1.0e-10

intpntQoTolMuRed

Default Value:

Relative complementarity gap feasibility tolerance used when interior-point optimizer is applied to a quadratic optimization problem.

Accepted Values: [0.0;1.0]

Default Value: 1.0e-8

Groups: Interior-point method, Termination criterion

intpntQoTolNearRel

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Accepted Values: $[1.0; +\inf]$

Default Value: 1000

Groups: Interior-point method, Termination criterion

intpntQoTolPfeas

Primal feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.

Accepted Values: [0.0;1.0]

Default Value: 1.0e-8

Groups: Interior-point method, Termination criterion

$\verb|intpntQoTolRelGap|$

Relative gap termination tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.

Accepted Values: [0.0;1.0]

 ${\tt Default\ Value:} \qquad 1.0e\text{-}8$

Groups: Interior-point method, Termination criterion

$\verb|intpntTolDfeas||$

Dual feasibility tolerance used for linear and quadratic optimization problems.

Accepted Values: [0.0; 1.0]

Default Value: 1.0e-8

 ${\tt Groups:} \quad \textit{Interior-point method, Termination criterion}$

intpntTolDsafe

Controls the initial dual starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Accepted Values: $[1.0e-4;+\inf]$

Default Value: 1.0

Groups: Interior-point method

intpntTolInfeas

Controls when the optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible. A value of 0.0 means the optimizer must have an exact certificate of infeasibility and this is very unlikely to happen.

Accepted Values: [0.0;1.0] Default Value: 1.0e-10

Groups: Interior-point method, Termination criterion, Nonlinear convex method

$\verb"intpntTolMuRed"$

Relative complementarity gap tolerance.

Accepted Values: [0.0;1.0] Default Value: 1.0e-16

 ${\tt Groups:} \quad \textit{Interior-point method, Termination criterion}$

intpntTolPath

Controls how close the interior-point optimizer follows the central path. A large value of this parameter means the central is followed very closely. On numerical unstable problems it may be worthwhile to increase this parameter.

Accepted Values: [0.0; 0.9999]

Default Value: 1.0e-8

Groups: Interior-point method

intpntTolPfeas

Primal feasibility tolerance used for linear and quadratic optimization problems.

Accepted Values: [0.0;1.0]

Default Value: 1.0e-8

Groups: Interior-point method, Termination criterion

intpntTolPsafe

Controls the initial primal starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it may be worthwhile to increase this value.

Accepted Values: $[1.0e-4;+\inf]$

Default Value: 1.0

 ${\tt Groups:} \quad \textit{Interior-point method}$

intpntTolRelGap

Relative gap termination tolerance.

Accepted Values: $[1.0e-14;+\inf]$

Default Value: 1.0e-8

Groups: Termination criterion, Interior-point method

$\verb|intpntTolRelStep|$

Relative step size to the boundary for linear and quadratic optimization problems.

Accepted Values: [1.0e-4;0.999999]

Default Value: 0.9999

Groups: Interior-point method

intpntTolStepSize

If the step size falls below the value of this parameter, then the interior-point optimizer assumes

13.4. Parameters 207

that it is stalled. In other words the interior-point optimizer does not make any progress and therefore it is better stop.

Accepted Values: [0.0;1.0]

Default Value: 1.0e-6

Groups: Interior-point method

lowerObjCut

If either a primal or dual feasible solution is found proving that the optimal objective value is outside, the interval [lowerObjCut , upperObjCut], then MOSEK is terminated.

Accepted Values: [-inf;+inf]

Default Value: -1.0e30

Groups: Termination criterion

lowerObjCutFiniteTrh

If the lower objective cut is less than the value of this parameter value, then the lower objective cut i.e. lower0bjCut is treated as $-\infty$.

Accepted Values: [-inf;+inf]

Default Value: -0.5e30

Groups: Termination criterion

mioDisableTermTime

This parameter specifies the number of seconds n during which the termination criteria governed by

- \bullet mioMaxNumRelaxs
- \bullet mioMaxNumBranches
- \bullet mioNearTolAbsGap
- $\bullet \textit{mioNearTolRelGap}$

is disabled since the beginning of the optimization.

A negative value is identical to infinity i.e. the termination criteria are never checked.

Accepted Values: $[-\inf; +\inf]$

Default Value: -1.0

Groups: Mixed-integer optimization, Termination criterion

mioMaxTime

This parameter limits the maximum time spent by the mixed-integer optimizer. A negative number means infinity.

Accepted Values: [-inf;+inf]

Default Value: -1.0

Groups: Mixed-integer optimization, Termination criterion

${\tt mioNearTolAbsGap}$

Relaxed absolute optimality tolerance employed by the mixed-integer optimizer. This termination criteria is delayed. See mioDisableTermTime for details.

Accepted Values: $[0.0; +\inf]$

Default Value: 0.0

Groups: Mixed-integer optimization

mioNearTolRelGap

The mixed-integer optimizer is terminated when this tolerance is satisfied. This termination criteria is delayed. See <code>mioDisableTermTime</code> for details.

Accepted Values: $[0.0 ; +\inf]$

Default Value: 1.0e-3

Groups: Mixed-integer optimization, Termination criterion

mioRelGapConst

This value is used to compute the relative gap for the solution to an integer optimization problem.

Accepted Values: [1.0e-15; +inf]

Default Value: 1.0e-10

Groups: Mixed-integer optimization, Termination criterion

mioTolAbsGap

Absolute optimality tolerance employed by the mixed-integer optimizer.

Accepted Values: $[0.0;+\inf]$

Default Value: 0.0

Groups: Mixed-integer optimization

mioTolAbsRelaxInt

Absolute relaxation tolerance of the integer constraints. I.e. $\min(|x| - \lfloor x \rfloor, \lceil x \rceil - |x|)$ is less than the tolerance then the integer restrictions assumed to be satisfied.

Accepted Values: [1e-9;+inf]

Default Value: 1.0e-5

Groups: Mixed-integer optimization

mioTolFeas

Feasibility tolerance for mixed integer solver.

Accepted Values: [1e-9;1e-3]

Default Value: 1.0e-6

Groups: Mixed-integer optimization

$\verb|mioTolRelDualBoundImprovement|\\$

If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation. A value of 0.0 means that the value is selected automatically.

Accepted Values: [0.0; 1.0]

 ${\tt Default\ Value:} \quad 0.0$

 ${\tt Groups:} \quad \textit{Mixed-integer optimization}$

${\tt mioTolRelGap}$

Relative optimality tolerance employed by the mixed-integer optimizer.

Accepted Values: $[0.0;+\inf]$

Default Value: 1.0e-4

Groups: Mixed-integer optimization, Termination criterion

optimizerMaxTime

Maximum amount of time the optimizer is allowed to spent on the optimization. A negative number means infinity.

Accepted Values: [-inf;+inf]

Default Value: -1.0

13.4. Parameters 209

Groups: Termination criterion

presolveTolAbsLindep

Absolute tolerance employed by the linear dependency checker.

Accepted Values: [0.0; +inf]

Default Value: 1.0e-6

Groups: Presolve

presolveTolAij

Absolute zero tolerance employed for a_{ij} in the presolve.

Accepted Values: [1.0e-15;+inf]

Default Value: 1.0e-12

PresolveGroups:

presolveTolRelLindep

Relative tolerance employed by the linear dependency checker.

 $[0.0; +\inf]$ Accepted Values:

Default Value: 1.0e-10

Groups: Presolve

presolveTolS

Absolute zero tolerance employed for s_i in the presolve.

Accepted Values: [0.0; +inf]

Default Value:

Groups: Presolve

presolveTolX

Absolute zero tolerance employed for x_i in the presolve.

Accepted Values: [0.0; +inf]

Default Value: 1.0e-8

Groups: Presolve

semidefiniteTolApprox

Tolerance to define a matrix to be positive semidefinite.

Accepted Values: [1.0e-15;+inf]

Default Value: 1.0e-10

Groups: Data check

simplexAbsTolPiv

Absolute pivot tolerance employed by the simplex optimizers.

Accepted Values: [1.0e-12;+inf]

Default Value: 1.0e-7

Simplex optimizer Groups:

simLuTolRelPiv

Relative pivot tolerance employed when computing the LU factorization of the basis in the simplex optimizers and in the basis identification procedure.

A value closer to 1.0 generally improves numerical stability but typically also implies an increase in the computational work.

Accepted Values: [1.0e-6; 0.999999] Default Value: 0.01

Groups: Basis identification, Simplex optimizer

upperObjCut

If either a primal or dual feasible solution is found proving that the optimal objective value is outside, the interval [lowerObjCut , upperObjCut], then MOSEK is terminated.

Accepted Values: [-inf;+inf]

Default Value: 1.0e30

Groups: Termination criterion

upperObjCutFiniteTrh

If the upper objective cut is greater than the value of this parameter, then the upper objective cut upper0bjCut is treated as ∞ .

Accepted Values: $[-\inf; +\inf]$

Default Value: 0.5e30

Groups: Termination criterion

Integer Parameters

${\tt autoUpdateSolInfo}$

Controls whether the solution information items are automatically updated after an optimization is performed.

Accepted Values: ON, OFF

Default Value: off

Groups: Optimization system

biCleanOptimizer

Controls which simplex optimizer is used in the clean-up phase.

Accepted Values: FREE, INTPNT, CONIC, PRIMAL SIMPLEX, DUAL SIMPLEX,

FREE SIMPLEX, MIXED_INT

Default Value: free

Groups: Basis identification, Overall solver

biIgnoreMaxIter

If the parameter *intpntBasis* has the value noError and the interior-point optimizer has terminated due to maximum number of iterations, then basis identification is performed if this parameter has the value on.

Accepted Values: ON, OFF

Default Value: off

Groups: Interior-point method, Basis identification

bilgnoreNumError

If the parameter *intpntBasis* has the value noError and the interior-point optimizer has terminated due to a numerical problem, then basis identification is performed if this parameter has the value on.

Accepted Values: ON, OFF

Default Value: off

Groups: Interior-point method, Basis identification

13.4. Parameters 211

biMaxIterations

Controls the maximum number of simplex iterations allowed to optimize a basis after the basis identification.

Accepted Values: $[0;+\inf]$ Default Value: 1000000

Groups: Basis identification, Termination criterion

cacheLicense

Specifies if the license is kept checked out for the lifetime of the mosek environment (on) or returned to the server immediately after the optimization (off).

By default the license is checked out for the lifetime of the **MOSEK** environment by the first call to the optimizer.

Check-in and check-out of licenses have an overhead. Frequent communication with the license server should be avoided.

Accepted Values: ON, OFF

Default Value: on

Groups: License manager

infeasPreferPrimal

If both certificates of primal and dual infeasibility are supplied then only the primal is used when this option is turned on.

Accepted Values: ON, OFF

Default Value: on Groups: Overall solver

${\tt intpntBasis}$

Controls whether the interior-point optimizer also computes an optimal basis.

Accepted Values: NEVER, ALWAYS, NO_ERROR, IF_FEASIBLE, RESERVERED

Default Value: always

 ${\tt Groups:} \quad \textit{Interior-point method, Basis identification}$

intpntDiffStep

Controls whether different step sizes are allowed in the primal and dual space.

Accepted Values: ON, OFF

Default Value: on

Groups: Interior-point method

intpntHotstart

Currently not in use.

Accepted Values: NONE, PRIMAL, DUAL, PRIMAL DUAL

Default Value: none

Groups: Interior-point method

$\verb|intpntMaxIterations||$

Controls the maximum number of iterations allowed in the interior-point optimizer.

Accepted Values: $[0;+\inf]$

Default Value: 400

Groups: Interior-point method, Termination criterion

intpntMaxNumCor

Controls the maximum number of correctors allowed by the multiple corrector procedure. A negative value means that **MOSEK** is making the choice.

Accepted Values: $[-1;+\inf]$

Default Value: -1

Groups: Interior-point method

intpntMaxNumRefinementSteps

Maximum number of steps to be used by the iterative refinement of the search direction. A negative value implies that the optimizer chooses the maximum number of iterative refinement steps.

Accepted Values: [-inf;+inf]

Default Value: -1

Groups: Interior-point method

intpntMultiThread

Controls whether the interior-point optimizers are allowed to employ multiple threads if more threads is available.

Accepted Values: ON, OFF

Default Value: on

Groups: Optimization system

intpntOffColTrh

Controls how many offending columns are detected in the Jacobian of the constraint matrix.

0	no detection
1	aggressive detection
> 1	higher values mean less aggressive detection

Accepted Values: $[0;+\inf]$

Default Value: 40

Groups: Interior-point method

$\verb|intpntOrderMethod||$

Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system.

 ${\tt Accepted\ Values:} \qquad {\tt FREE}, \quad {\tt APPMINLOC}, \quad {\tt EXPERIMENTAL}, \quad {\tt TRY_GRAPHPAR},$

FORCE GRAPHPAR, NONE

Default Value: free

Groups: Interior-point method

$\verb|intpntRegularization| Use \\$

Controls whether regularization is allowed.

Accepted Values: ON, OFF

Default Value: on

 ${\tt Groups:} \quad \textit{Interior-point method}$

intpntScaling

Controls how the problem is scaled before the interior-point optimizer is used.

Accepted Values: FREE, NONE, MODERATE, AGGRESSIVE

Default Value: free

Groups: Interior-point method

intpntSolveForm

Controls whether the primal or the dual problem is solved.

Accepted Values: FREE, PRIMAL, DUAL

Default Value: free

 ${\tt Groups:} \quad \textit{Interior-point method}$

intpntStartingPoint

Starting point used by the interior-point optimizer.

Accepted Values: FREE, GUESS, CONSTANT, SATISFY BOUNDS

Default Value: free

Groups: Interior-point method

licenseDebug

This option is used to turn on debugging of the license manager.

Accepted Values: ON, OFF

Default Value: off

Groups: License manager

licensePauseTime

If licenseWait =on and no license is available, then MOSEK sleeps a number of milliseconds between each check of whether a license has become free.

Accepted Values: [0;1000000]

Default Value: 100

Groups: License manager

${\tt licenseSuppressExpireWrns}$

Controls whether license features expire warnings are suppressed.

Accepted Values: ON, OFF

Default Value: off

Groups: License manager, Output information

licenseTrhExpiryWrn

If a license feature expires in a numbers days less than the value of this parameter then a warning will be issued.

Accepted Values: $[0;+\inf]$

Default Value: 7

licenseWait

If all licenses are in use **MOSEK** returns with an error code. However, by turning on this parameter **MOSEK** will wait for an available license.

Accepted Values: ON, OFF

Default Value: off

Groups: Overall solver, Optimization system, License manager

log

Controls the amount of log information. The value 0 implies that all log information is suppressed. A higher level implies that more information is logged.

Please note that if a task is employed to solve a sequence of optimization problems the value of this parameter is reduced by the value of logCutSecondOpt for the second and any subsequent optimizations.

Accepted Values: $[0;+\inf]$

```
Default Value: 10
```

Groups: Output information, Logging

logAnaPro

Controls amount of output from the problem analyzer.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Analysis, Logging

logBi

Controls the amount of output printed by the basis identification procedure. A higher level implies that more information is logged.

Accepted Values: $[0;+\inf]$

Default Value: 4

Groups: Basis identification, Output information, Logging

logBiFreq

Controls how frequent the optimizer outputs information about the basis identification and how frequent the user-defined call-back function is called.

Accepted Values: $[0;+\inf]$

Default Value: 2500

Groups: Basis identification, Output information, Logging

logCutSecondOpt

If a task is employed to solve a sequence of optimization problems, then the value of the log levels is reduced by the value of this parameter. E.g log and logSim are reduced by the value of this parameter for the second and any subsequent optimizations.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Output information, Logging

logExpand

Controls the amount of logging when a data item such as the maximum number constrains is expanded.

Accepted Values: $[0;+\inf]$

Default Value: 0

Groups: Output information, Logging

logFactor

If turned on, then the factor log lines are added to the log.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Output information, Logging

logFile

If turned on, then some log info is printed when a file is written or read.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Data input/output, Output information, Logging

logHead

If turned on, then a header line is added to the log.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Output information, Logging

logInfeasAna

Controls amount of output printed by the infeasibility analyzer procedures. A higher level implies that more information is logged.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Infeasibility report, Output information, Logging

logIntpnt

Controls amount of output printed by the interior-point optimizer. A higher level implies that more information is logged.

Accepted Values: $[0;+\inf]$

Default Value: 4

Groups: Interior-point method, Output information, Logging

logMio

Controls the log level for the mixed-integer optimizer. A higher level implies that more information is logged.

Accepted Values: $[0;+\inf]$

Default Value: 4

Groups: Mixed-integer optimization, Output information, Logging

logMioFreq

Controls how frequent the mixed-integer optimizer prints the log line. It will print line every time <code>logMioFreq</code> relaxations have been solved.

Accepted Values: $[-\inf; +\inf]$

Default Value: 10

Groups: Mixed-integer optimization, Output information, Logging

logOptimizer

Controls the amount of general optimizer information that is logged.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Output information, Logging

logOrder

If turned on, then factor lines are added to the log.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Output information, Logging

logPresolve

216

Controls amount of output printed by the presolve procedure. A higher level implies that more information is logged.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Interior-point method, Logging

logResponse

Controls amount of output printed when response codes are reported. A higher level implies that more information is logged.

Accepted Values: $[0;+\inf]$

Default Value: 0

Groups: Output information, Logging

logSim

Controls amount of output printed by the simplex optimizer. A higher level implies that more information is logged.

Accepted Values: $[0;+\inf]$

Default Value: 4

Groups: Simplex optimizer, Output information, Logging

logSimFreq

Controls how frequent the simplex optimizer outputs information about the optimization and how frequent the user-defined call-back function is called.

Accepted Values: $[0;+\inf]$

Default Value: 1000

Groups: Simplex optimizer, Output information, Logging

logSimMinor

Currently not in use.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Simplex optimizer, Output information

logStorage

When turned on, MOSEK prints messages regarding the storage usage and allocation.

Accepted Values: $[0;+\inf]$

Default Value: 0

Groups: Output information, Optimization system, Logging

maxNumWarnings

Each warning is shown a limit number times controlled by this parameter. A negative value is identical to infinite number of times.

Accepted Values: [-inf;+inf]

Default Value: 10

Groups: Output information

mioBranchDir

Controls whether the mixed-integer optimizer is branching up or down by default.

Accepted Values: FREE, UP, DOWN, NEAR, FAR, ROOT LP, GUIDED, PSEUDOCOST

Default Value: free

Groups: Mixed-integer optimization

mioConstructSol

If set to on and all integer variables have been given a value for which a feasible mixed integer solution exists, then **MOSEK** generates an initial solution to the mixed integer problem by fixing all integer values and solving the remaining problem.

Accepted Values: ON, OFF

Default Value: off

Groups: Mixed-integer optimization

mioCutClique

Controls whether clique cuts should be generated.

Accepted Values: ON, OFF

Default Value: on

Groups: Mixed-integer optimization

mioCutCmir

Controls whether mixed integer rounding cuts should be generated.

Accepted Values: ON, OFF

Default Value: on

 ${\tt Groups:} \quad \textit{Mixed-integer optimization}$

mioCutGmi

Controls whether GMI cuts should be generated.

Accepted Values: ON, OFF

Default Value: on

 ${\tt Groups:} \quad \textit{Mixed-integer optimization}$

mioCutImpliedBound

Controls whether implied bound cuts should be generated.

Accepted Values: ON, OFF

Default Value: off

 ${\tt Groups:} \quad \textit{Mixed-integer optimization}$

${\tt mioCutKnapsackCover}$

Controls whether knapsack cover cuts should be generated.

Accepted Values: ON, OFF

Default Value: off

Groups: Mixed-integer optimization

mioCutSelectionLevel

Controls how aggressively generated cuts are selected to be included in the relaxation.

-1. The optimizer chooses the level of cut selection

 $0. \\ \\ Generated$ cuts less likely to be added to the relaxation

1.Cuts are more aggressively selected to be included in the relaxation

Accepted Values: [-1;+1]

Default Value: -1

 ${\tt Groups:} \quad \textit{Mixed-integer optimization}$

mioHeuristicLevel

Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution. A value of zero means the heuristic is not used at all. A larger value than 0 means that a gradually more sophisticated heuristic is used which is computationally more expensive. A negative value implies that the optimizer chooses the heuristic. Normally a value around 3 to 5 should be optimal.

Accepted Values: [-inf;+inf]

Default Value: -1

Groups: Mixed-integer optimization

mioMaxNumBranches

Maximum number of branches allowed during the branch and bound search. A negative value means infinite.

Accepted Values: $[-\inf; +\inf]$

Default Value: -1

Groups: Mixed-integer optimization, Termination criterion

mioMaxNumRelaxs

Maximum number of relaxations allowed during the branch and bound search. A negative value means infinite.

Accepted Values: $[-\inf; +\inf]$

Default Value: -1

Groups: Mixed-integer optimization

mioMaxNumSolutions

The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located. If this parameter has the value n > 0, then the mixed-integer optimizer will be terminated when n feasible solutions have been located.

Accepted Values: [-inf;+inf]

Default Value: -1

Groups: Mixed-integer optimization, Termination criterion

mioMode

Controls whether the optimizer includes the integer restrictions when solving a (mixed) integer optimization problem.

Accepted Values: IGNORED, SATISFIED

Default Value: satisfied

Groups: Overall solver

${\tt mioMtUserCb}$

It true user callbacks are called from each thread used by this optimizer. If false the user callback is only called from a single thread.

Accepted Values: ON, OFF

Default Value: off

Groups: Optimization system

mioNodeOptimizer

Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer.

Accepted Values: FREE, INTPNT, CONIC, PRIMAL_SIMPLEX, DUAL_SIMPLEX, FREE SIMPLEX, MIXED INT

----=

Default Value: free

Groups: Mixed-integer optimization

mioNodeSelection

Controls the node selection strategy employed by the mixed-integer optimizer.

Accepted Values: FREE, FIRST, BEST, WORST, HYBRID, PSEUDO

Default Value: free

Groups: Mixed-integer optimization

mioPerspectiveReformulate

Enables or disables perspective reformulation in presolve.

Accepted Values: ON, OFF

Default Value: on

Groups: Mixed-integer optimization

mioProbingLevel

Controls the amount of probing employed by the mixed-integer optimizer in presolve.

- -1. The optimizer chooses the level of probing employed
 - 0.Probing is disabled
 - 1.A low amount of probing is employed
 - 2.A medium amount of probing is employed
 - 3.A high amount of probing is employed

Accepted Values: [-inf;+inf]

Default Value: -1

Groups: Mixed-integer optimization

mioRinsMaxNodes

Controls the maximum number of nodes allowed in each call to the RINS heuristic. The default value of -1 means that the value is determined automatically. A value of zero turns off the heuristic.

Accepted Values: $[-1;+\inf]$

Default Value: -1

Groups: Mixed-integer optimization

mioRootOptimizer

Controls which optimizer is employed at the root node in the mixed-integer optimizer.

Accepted Values: FREE, INTPNT, CONIC, PRIMAL_SIMPLEX, DUAL_SIMPLEX,

FREE SIMPLEX, MIXED INT

Default Value: free

 ${\tt Groups:} \quad \textit{Mixed-integer optimization}$

mioRootRepeatPresolveLevel

Controls whether presolve can be repeated at root node.

- •-1 The optimizer chooses whether presolve is repeated
- ullet 0 Never repeat presolve
- •1 Always repeat presolve

Accepted Values: [-1;1]

Default Value: -1

 ${\tt Groups:} \quad \textit{Mixed-integer optimization}$

mioVbDetectionLevel

Controls how much effort is put into detecting variable bounds.

- -1. The optimizer chooses
 - 0.No variable bounds are detected
 - 1. Only detect variable bounds that are directly represented in the problem
 - 2.Detect variable bounds in probing

```
Accepted Values: [-1;+2]
```

Default Value: -1

Groups: Mixed-integer optimization

mtSpincount

Set the number of iterations to spin before sleeping.

Accepted Values: [0;1000000000]

Default Value: 0

Groups: Optimization system

numThreads

Controls the number of threads employed by the optimizer. If set to 0 the number of threads used will be equal to the number of cores detected on the machine.

Accepted Values: $[0;+\inf]$

Default Value: 0

Groups: Optimization system

optimizer

The parameter controls which optimizer is used to optimize the task.

Accepted Values: FREE, INTPNT, CONIC, PRIMAL_SIMPLEX, DUAL_SIMPLEX,

FREE SIMPLEX, MIXED INT

Default Value: free

Groups: Overall solver

presolveEliminatorMaxFill

Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of the presolve. A negative value menas the parameter value is selected automatically.

Accepted Values: $[-\inf; +\inf]$

Default Value: -1

 ${\tt Groups:} \quad \textit{Presolve}$

${\tt presolveEliminatorMaxNumTries}$

Control the maximum number of times the eliminator is tried.

Accepted Values: [-inf;+inf]

Default Value: -1

Groups: Presolve

presolveLevel

Currently not used.

Accepted Values: [-inf;+inf]

Default Value: -1

Groups: Overall solver, Presolve

presolveLindepAbsWorkTrh

The linear dependency check is potentially computationally expensive.

Accepted Values: [-inf;+inf]

 $\begin{array}{lll} {\tt Default\ Value:} & 10 \\ {\tt Groups:} & {\tt \it Presolve} \end{array}$

presolveLindepRelWorkTrh

The linear dependency check is potentially computationally expensive.

Accepted Values: [-inf;+inf]

Default Value: 100
Groups: Presolve

presolveLindepUse

Controls whether the linear constraints are checked for linear dependencies.

Accepted Values: ON, OFF

 $\begin{array}{ll} {\tt Default\ Value:} & {\tt on} \\ {\tt Groups:} & {\tt \it Presolve} \end{array}$

${\tt presolveMaxNumReductions}$

Controls the maximum number of reductions performed by the presolve. The value of the parameter is normally only changed in connection with debugging. A negative value implies that an infinite number of reductions are allowed.

Accepted Values: $[-\inf; +\inf]$

Default Value: -1

presolveUse

Controls whether the presolve is applied to a problem before it is optimized.

Accepted Values: OFF, ON, FREE

Default Value: free

Groups: Overall solver, Presolve

simBasisFactorUse

Controls whether a (LU) factorization of the basis is used in a hot-start. Forcing a refactorization sometimes improves the stability of the simplex optimizers, but in most cases there is a performance penalty.

Accepted Values: ON, OFF

Default Value: on

Groups: Simplex optimizer

simDegen

Controls how aggressively degeneration is handled.

Accepted Values: NONE, FREE, AGGRESSIVE, MODERATE, MINIMUM

Default Value: free

Groups: Simplex optimizer

simDualCrash

Controls whether crashing is performed in the dual simplex optimizer.

If this parameter is set to x, then a crash will be performed if a basis consists of more than (100-x) mod f_v entries, where f_v is the number of fixed variables.

Accepted Values: $[0;+\inf]$

Default Value: 90

Groups: Dual simplex optimizer

simDualPhaseoneMethod

An experimental feature.

Accepted Values: [0;10]

Default Value: 0

Groups: Simplex optimizer

simDualRestrictSelection

The dual simplex optimizer can use a so-called restricted selection/pricing strategy to chooses the outgoing variable. Hence, if restricted selection is applied, then the dual simplex optimizer first choose a subset of all the potential outgoing variables. Next, for some time it will choose the outgoing variable only among the subset. From time to time the subset is redefined.

A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Accepted Values: [0;100]

Default Value: 50

Groups: Dual simplex optimizer

simDualSelection

Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer.

Accepted Values: FREE, FULL, ASE, DEVEX, SE, PARTIAL

Default Value: free

Groups: Dual simplex optimizer

simExploitDupvec

Controls if the simplex optimizers are allowed to exploit duplicated columns.

Accepted Values: ON, OFF, FREE

Default Value: off

Groups: Simplex optimizer

simHotstart

Controls the type of hot-start that the simplex optimizer perform.

Accepted Values: NONE, FREE, STATUS KEYS

Default Value: free

Groups: Simplex optimizer

simHotstartLu

Determines if the simplex optimizer should exploit the initial factorization.

Accepted Values: ON, OFF

Default Value: on

simInteger

An experimental feature.

Accepted Values: [0;10]

Default Value: 0

Groups: Simplex optimizer

simMaxIterations

Maximum number of iterations that can be used by a simplex optimizer.

Accepted Values: $[0;+\inf]$ Default Value: 10000000

Groups: Simplex optimizer, Termination criterion

simMaxNumSetbacks

Controls how many set-backs are allowed within a simplex optimizer. A set-back is an event where the optimizer moves in the wrong direction. This is impossible in theory but may happen due to numerical problems.

Accepted Values: $[0;+\inf]$

Default Value: 250

Groups: Simplex optimizer

simNonSingular

Controls if the simplex optimizer ensures a non-singular basis, if possible.

Accepted Values: ON, OFF

Default Value: on

Groups: Simplex optimizer

simPrimalCrash

Controls whether crashing is performed in the primal simplex optimizer.

In general, if a basis consists of more than (100-this parameter value)% fixed variables, then a crash will be performed.

Accepted Values: $[0;+\inf]$

Default Value: 90

 ${\tt Groups:} \quad \textit{Primal simplex optimizer}$

simPrimalPhaseoneMethod

An experimental feature.

Accepted Values: [0;10]

 ${\tt Default\ Value:} \quad 0$

Groups: Simplex optimizer

simPrimalRestrictSelection

The primal simplex optimizer can use a so-called restricted selection/pricing strategy to chooses the outgoing variable. Hence, if restricted selection is applied, then the primal simplex optimizer first choose a subset of all the potential incoming variables. Next, for some time it will choose the incoming variable only among the subset. From time to time the subset is redefined.

A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Accepted Values: [0;100]

Default Value: 50

 ${\tt Groups:} \quad \textit{Primal simplex optimizer}$

simPrimalSelection

Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer.

Accepted Values: FREE, FULL, ASE, DEVEX, SE, PARTIAL

Default Value: free

Groups: Primal simplex optimizer

simRefactorFreq

Controls how frequent the basis is refactorized. The value 0 means that the optimizer determines the best point of refactorization.

It is strongly recommended NOT to change this parameter.

Accepted Values: $[0;+\inf]$

Default Value: 0

Groups: Simplex optimizer

simReformulation

Controls if the simplex optimizers are allowed to reformulate the problem.

Accepted Values: ON, OFF, FREE, AGGRESSIVE

Default Value: off

Groups: Simplex optimizer

simSaveLu

Controls if the LU factorization stored should be replaced with the LU factorization corresponding to the initial basis.

Accepted Values: ON, OFF

Default Value: off

Groups: Simplex optimizer

simScaling

Controls how much effort is used in scaling the problem before a simplex optimizer is used.

Accepted Values: FREE, NONE, MODERATE, AGGRESSIVE

Default Value: free

Groups: Simplex optimizer

simScalingMethod

Controls how the problem is scaled before a simplex optimizer is used.

Accepted Values: POW2, FREE

 ${\tt Default\ Value:} \quad pow 2$

Groups: Simplex optimizer

simSolveForm

Controls whether the primal or the dual problem is solved by the primal-/dual-simplex optimizer.

Accepted Values: FREE, PRIMAL, DUAL

Default Value: free

Groups: Simplex optimizer

simStabilityPriority

Controls how high priority the numerical stability should be given.

Accepted Values: [0;100]

 ${\tt Default\ Value:} \quad 50$

Groups: Simplex optimizer

simSwitchOptimizer

The simplex optimizer sometimes chooses to solve the dual problem instead of the primal problem. This implies that if you have chosen to use the dual simplex optimizer and the problem is dualized, then it actually makes sense to use the primal simplex optimizer instead. If this parameter is on

and the problem is dualized and furthermore the simplex optimizer is chosen to be the primal (dual) one, then it is switched to the dual (primal).

Accepted Values: ON, OFF

Default Value: off

Groups: Simplex optimizer

timingLevel

Controls the a amount of timing performed inside MOSEK.

Accepted Values: $[0;+\inf]$

Default Value: 1

Groups: Optimization system

writeLpFullObj

Write all variables, including the ones with 0-coefficients, in the objective.

Accepted Values: ON, OFF

Default Value: on

Groups: Data input/output

writeLpLineWidth

Maximum width of line in an LP file written by MOSEK.

Accepted Values: $[40;+\inf]$

Default Value: 80

Groups: Data input/output

writeLpQuotedNames

If this option is turned on, then MOSEK will quote invalid LP names when writing an LP file.

Accepted Values: ON, OFF

Default Value: on

Groups: Data input/output

writeLpTermsPerLine

Maximum number of terms on a single line in an LP file written by MOSEK. 0 means unlimited.

Accepted Values: $[0;+\inf]$

Default Value: 10

 ${\tt Groups:} \quad \textit{Data input/output}$

String Parameters

basSolFileName

Name of the bas solution file.

Accepted Values: Any valid file name.

Groups: Data input/output, Solution input/output

dataFileName

Data are read and written to this file.

Accepted Values: Any valid file name.

 ${\tt Groups:} \quad \textit{Data input/output}$

debugFileName

MOSEK debug file.

Accepted Values: Any valid file name.

Groups: Data input/output

intSolFileName

Name of the int solution file.

Accepted Values: Any valid file name.

Groups: Data input/output, Solution input/output

itrSolFileName

Name of the itr solution file.

Accepted Values: Any valid file name.

Groups: Data input/output, Solution input/output

mioDebugString

For internal use only.

Accepted Values: Any valid string.

Groups: Data input/output

paramCommentSign

Only the first character in this string is used. It is considered as a start of comment sign in the **MOSEK** parameter file. Spaces are ignored in the string.

Accepted Values: Any valid string.

Default Value: %%

 ${\tt Groups:} \quad \textit{Data input/output}$

paramReadFileName

Modifications to the parameter database is read from this file.

Accepted Values: Any valid file name.

 ${\tt Groups:} \quad \textit{Data input/output}$

paramWriteFileName

The parameter database is written to this file.

Accepted Values: Any valid file name.

 ${\tt Groups:} \quad \textit{Data input/output}$

readMpsBouName

Name of the BOUNDS vector used. An empty name means that the first BOUNDS vector is used.

Accepted Values: Any valid MPS name.

 ${\tt Groups:} \quad \textit{Data input/output}$

readMpsObjName

Name of the free constraint used as objective function. An empty name means that the first constraint is used as objective function.

Accepted Values: Any valid MPS name.

 ${\tt Groups:} \quad \textit{Data input/output}$

${\tt readMpsRanName}$

Name of the RANGE vector used. An empty name means that the first RANGE vector is used.

Accepted Values: Any valid MPS name.

Groups: Data input/output

readMpsRhsName

Name of the RHS used. An empty name means that the first RHS vector is used.

Accepted Values: Any valid MPS name.

Groups: Data input/output

remoteAccessToken

An access token used to submit tasks to a remote **MOSEK** server. An access token is a random 32-byte string encoded in base64, i.e. it is a 44 character ASCII string.

Accepted Values: Any valid string.

solFilterXcLow

A filter used to determine which constraints should be listed in the solution file. A value of 0.5 means that all constraints having xc[i]>0.5 should be listed, whereas +0.5 means that all constraints having xc[i]>=blc[i]+0.5 should be listed. An empty filter means that no filter is applied.

Accepted Values: Any valid filter.

Groups: Data input/output, Solution input/output

solFilterXcUpr

A filter used to determine which constraints should be listed in the solution file. A value of 0.5 means that all constraints having xc[i]<0.5 should be listed, whereas -0.5 means all constraints having xc[i]<=buc[i]-0.5 should be listed. An empty filter means that no filter is applied.

Accepted Values: Any valid filter.

Groups: Data input/output, Solution input/output

solFilterXxLow

A filter used to determine which variables should be listed in the solution file. A value of "0.5" means that all constraints having xx[j] >= 0.5 should be listed, whereas "+0.5" means that all constraints having xx[j] >= blx[j] + 0.5 should be listed. An empty filter means no filter is applied.

Accepted Values: Any valid filter.

 ${\tt Groups:} \quad \textit{Data input/output, Solution input/output}$

solFilterXxUpr

A filter used to determine which variables should be listed in the solution file. A value of "0.5" means that all constraints having xx[j]<0.5 should be printed, whereas "-0.5" means all constraints having xx[j]<=bux[j]-0.5 should be listed. An empty filter means no filter is applied.

Accepted Values: Any valid file name.

Groups: Data input/output, Solution input/output

statFileName

Statistics file name.

Accepted Values: Any valid file name.

Groups: Data input/output

statKey

Key used when writing the summary file.

Accepted Values: Any valid XML string.

 ${\tt Groups:} \quad \textit{Data input/output}$

statName

Name used when writing the statistics file.

Accepted Values: Any valid XML string.

Groups: Data input/output

writeLpGenVarName

Sometimes when an LP file is written additional variables must be inserted. They will have the prefix denoted by this parameter.

Accepted Values: Any valid string.

SUPPORTED FILE FORMATS

MOSEK supports a range of problem and solution formats listed in Table 14.1 and Table 14.2. The **Task** format is MOSEK's native binary format and it supports all features that MOSEK supports. The **OPF** format is MOSEK's human-readable alternative that supports nearly all features (everything except semidefinite problems). In general, text formats are significantly slower to read, but can be examined and edited directly in any text editor.

Problem formats

See Table 14.1.

Table 14.1: List of supported file formats for optimization problems.

Format Type	Ext.	Binary/Text	LP	QP	CQO	SDP
LP	lp	plain text	X	X		
MPS	mps	plain text	X	X		
OPF	opf	plain text	X	X	X	
CBF	cbf	plain text	X		X	X
Osil	xml	xml text	X	X		
Task format	task	binary	X	X	X	X
Jtask format	jtask	text	X	X	X	X

Solution formats

See Table 14.2.

Table 14.2: List of supported solution formats.

Format Type	Ext.	Binary/Text	Description
	sol	plain text	Interior Solution
SOL	bas	plain text	Basic Solution
	int	plain text	Integer
Jsol format	jsol	text	Solution

Compression

MOSEK supports GZIP compression of files. Problem files with an additional .gz extension are assumed to be compressed when read, and are automatically compressed when written. For example, a file called

problem.mps.gz

will be considered as a GZIP compressed MPS file.

14.1 The LP File Format

MOSEK supports the LP file format with some extensions. The LP format is not a completely well-defined standard and hence different optimization packages may interpret the same LP file in slightly different ways. MOSEK tries to emulate as closely as possible CPLEX's behavior, but tries to stay backward compatible.

The LP file format can specify problems on the form

$$\begin{array}{lll} \text{minimize/maximize} & & c^Tx + \frac{1}{2}q^o(x) \\ \text{subject to} & l^c & \leq & Ax + \frac{1}{2}q(x) & \leq & u^c, \\ l^x & \leq & x & \leq & u^x, \\ & & & x_{\mathcal{J}} \text{ integer,} \end{array}$$

where

- $x \in \mathbb{R}^n$ is the vector of decision variables.
- $c \in \mathbb{R}^n$ is the linear term in the objective.
- $q^o :\in \mathbb{R}^n \to \mathbb{R}$ is the quadratic term in the objective where

$$q^o(x) = x^T Q^o x$$

and it is assumed that

$$Q^o = (Q^o)^T.$$

- $A \in \mathbb{R}^{m \times n}$ is the constraint matrix.
- $l^c \in \mathbb{R}^m$ is the lower limit on the activity for the constraints.
- $u^c \in \mathbb{R}^m$ is the upper limit on the activity for the constraints.
- $l^x \in \mathbb{R}^n$ is the lower limit on the activity for the variables.
- $u^x \in \mathbb{R}^n$ is the upper limit on the activity for the variables.
- $q: \mathbb{R}^n \to \mathbb{R}$ is a vector of quadratic functions. Hence,

$$q_i(x) = x^T Q^i x$$

where it is assumed that

$$Q^i = (Q^i)^T$$
.

• $\mathcal{J} \subseteq \{1, 2, \dots, n\}$ is an index set of the integer constrained variables.

14.1.1 File Sections

An LP formatted file contains a number of sections specifying the objective, constraints, variable bounds, and variable types. The section keywords may be any mix of upper and lower case letters.

Objective Function

The first section beginning with one of the keywords

max
maximum
maximize
min
minimum
minimize

defines the objective sense and the objective function, i.e.

$$c^T x + \frac{1}{2} x^T Q^o x.$$

The objective may be given a name by writing

myname:

before the expressions. If no name is given, then the objective is named obj.

The objective function contains linear and quadratic terms. The linear terms are written as:

```
4 x1 + x2 - 0.1 x3
```

and so forth. The quadratic terms are written in square brackets ([]) and are either squared or multiplied as in the examples

```
x1^2
```

and

```
x1 * x2
```

There may be zero or more pairs of brackets containing quadratic expressions.

An example of an objective section is

```
minimize
myobj: 4 x1 + x2 - 0.1 x3 + [ x1^2 + 2.1 x1 * x2 ]/2
```

Please note that the quadratic expressions are multiplied with $\frac{1}{2}$, so that the above expression means

minimize
$$4x_1 + x_2 - 0.1 \cdot x_3 + \frac{1}{2}(x_1^2 + 2.1 \cdot x_1 \cdot x_2)$$

If the same variable occurs more than once in the linear part, the coefficients are added, so that $4 \times 1 + 2 \times 1$ is equivalent to 6×1 . In the quadratic expressions $\times 1 \times 2$ is equivalent to $\times 2 \times 1$ and, as in the linear part, if the same variables multiplied or squared occur several times their coefficients are added.

Constraints

The second section beginning with one of the keywords

```
subj to
subject to
s.t.
st
```

defines the linear constraint matrix A and the quadratic matrices Q^i .

A constraint contains a name (optional), expressions adhering to the same rules as in the objective and a bound:

```
subject to con1: x1 + x2 + [ x3^2 ]/2 <= 5.1
```

The bound type (here <=) may be any of <, <=, =, >, >= (< and <= mean the same), and the bound may be any number.

In the standard LP format it is not possible to define more than one bound, but **MOSEK** supports defining ranged constraints by using double-colon (::) instead of a single-colon (:) after the constraint name, i.e.

$$-5 \le x_1 + x_2 \le 5 \tag{14.1}$$

may be written as

```
con:: -5 < x_1 + x_2 < 5
```

By default MOSEK writes ranged constraints this way.

If the files must adhere to the LP standard, ranged constraints must either be split into upper bounded and lower bounded constraints or be written as an equality with a slack variable. For example the expression (14.1) may be written as

$$x_1 + x_2 - sl_1 = 0, -5 \le sl_1 \le 5.$$

Bounds

Bounds on the variables can be specified in the bound section beginning with one of the keywords

```
bound bounds
```

The bounds section is optional but should, if present, follow the subject to section. All variables listed in the bounds section must occur in either the objective or a constraint.

The default lower and upper bounds are 0 and $+\infty$. A variable may be declared free with the keyword free, which means that the lower bound is $-\infty$ and the upper bound is $+\infty$. Furthermore it may be assigned a finite lower and upper bound. The bound definitions for a given variable may be written in one or two lines, and bounds can be any number or $\pm\infty$ (written as $+\inf/-\inf/+\inf\inf\inf_{-\inf}$) as in the example

```
bounds

x1 free

x2 <= 5

0.1 <= x2

x3 = 42

2 <= x4 < +inf
```

Variable Types

The final two sections are optional and must begin with one of the keywords

```
bin
binaries
binary
```

and

```
gen
general
```

Under general all integer variables are listed, and under binary all binary (integer variables with bounds 0 and 1) are listed:

```
general
x1 x2
binary
x3 x4
```

Again, all variables listed in the binary or general sections must occur in either the objective or a constraint.

Terminating Section

Finally, an LP formatted file must be terminated with the keyword

end

14.1.2 LP File Examples

Linear example lo1.lp

```
\ File: lo1.lp
maximize
obj: 3 x1 + x2 + 5 x3 + x4
subject to
c1: 3 x1 + x2 + 2 x3 = 30
c2: 2 x1 + x2 + 3 x3 + x4 >= 15
c3: 2 x2 + 3 x4 <= 25
bounds
0 <= x1 <= +infinity
0 <= x2 <= 10
0 <= x3 <= +infinity
0 <= x4 <= +infinity
end</pre>
```

Mixed integer example milo1.lp

```
maximize
obj: x1 + 6.4e-01 x2
subject to
c1: 5e+01 x1 + 3.1e+01 x2 <= 2.5e+02
c2: 3e+00 x1 - 2e+00 x2 >= -4e+00
bounds
0 <= x1 <= +infinity
0 <= x2 <= +infinity
general
x1 x2
end
```

14.1.3 LP Format peculiarities

Comments

Anything on a line after a \ is ignored and is treated as a comment.

Names

A name for an objective, a constraint or a variable may contain the letters a-z, A-Z, the digits θ - θ and the characters

```
!"#$%&()/,.;?@_'`|~
```

The first character in a name must not be a number, a period or the letter e or E. Keywords must not be used as names.

MOSEK accepts any character as valid for names, except \0. A name that is not allowed in LP file will be changed and a warning will be issued.

The algorithm for making names LP valid works as follows: The name is interpreted as an utf-8 string. For a unicode character c:

- If c==_ (underscore), the output is __ (two underscores).
- If c is a valid LP name character, the output is just c.
- If c is another character in the ASCII range, the output is <code>_XX</code>, where <code>XX</code> is the hexadecimal code for the character.
- If c is a character in the range 127-65535, the output is _uxxxx, where xxxx is the hexadecimal code for the character.
- If c is a character above 65535, the output is _UXXXXXXXX, where XXXXXXXX is the hexadecimal code for the character.

Invalid $\mathtt{utf-8}$ substrings are escaped as $\mathtt{LXX'}$, and if a name starts with a period, e or E, that character is escaped as \mathtt{LXX} .

Variable Bounds

Specifying several upper or lower bounds on one variable is possible but **MOSEK** uses only the tightest bounds. If a variable is fixed (with =), then it is considered the tightest bound.

MOSEK Extensions to the LP Format

Some optimization software packages employ a more strict definition of the LP format than the one used by **MOSEK**. The limitations imposed by the strict LP format are the following:

- Quadratic terms in the constraints are not allowed.
- Names can be only 16 characters long.
- Lines must not exceed 255 characters in length.

To get around some of the inconveniences converting from other problem formats, **MOSEK** allows lines to contain 1024 characters and names may have any length (shorter than the 1024 characters).

14.1.4 Formatting of an LP File

A few parameters control the visual formatting of LP files written by **MOSEK** in order to make it easier to read the files. These parameters are

- writeLpLineWidth
- writeLpTermsPerLine

The first parameter sets the maximum number of characters on a single line. The default value is 80 corresponding roughly to the width of a standard text document.

The second parameter sets the maximum number of terms per line; a term means a sign, a coefficient, and a name (for example + 42 elephants). The default value is 0, meaning that there is no maximum.

Unnamed Constraints

Reading and writing an LP file with **MOSEK** may change it superficially. If an LP file contains unnamed constraints or objective these are given their generic names when the file is read (however unnamed constraints in **MOSEK** are written without names).

14.2 The MPS File Format

MOSEK supports the standard MPS format with some extensions. For a detailed description of the MPS format see the book by Nazareth [Naz87].

14.2.1 MPS File Structure

The version of the MPS format supported by \mathbf{MOSEK} allows specification of an optimization problem of the form

$$\begin{array}{ccccc}
l^{c} & \leq & Ax + q(x) & \leq & u^{c}, \\
l^{x} & \leq & x & \leq & u^{x}, \\
& & x \in \mathcal{K}, \\
& & x_{\mathcal{T}} & \text{integer},
\end{array} (14.2)$$

where

- $x \in \mathbb{R}^n$ is the vector of decision variables.
- $A \in \mathbb{R}^{m \times n}$ is the constraint matrix.
- $l^c \in \mathbb{R}^m$ is the lower limit on the activity for the constraints.
- $u^c \in \mathbb{R}^m$ is the upper limit on the activity for the constraints.
- $l^x \in \mathbb{R}^n$ is the lower limit on the activity for the variables.
- $u^x \in \mathbb{R}^n$ is the upper limit on the activity for the variables.
- $q: \mathbb{R}^n \to \mathbb{R}$ is a vector of quadratic functions. Hence,

$$q_i(x) = \frac{1}{2}x^T Q^i x$$

where it is assumed that

$$Q^i = (Q^i)^T$$
.

Please note the explicit $\frac{1}{2}$ in the quadratic term and that Q^i is required to be symmetric.

- \mathcal{K} is a convex cone.
- $\mathcal{J} \subseteq \{1, 2, \dots, n\}$ is an index set of the integer-constrained variables.

An MPS file with one row and one column can be illustrated like this:

* 1 2 3 4 5 6
*2345678901234567890123456789012345678901234567890

[vname1]
ENDATA
```

Here the names in capitals are keywords of the MPS format and names in brackets are custom defined names or values. A couple of notes on the structure:

• Fields: All items surrounded by brackets appear in *fields*. The fields named "valueN" are numerical values. Hence, they must have the format

```
[+|-]XXXXXXX.XXXXXX[[e|E][+|-]XXX]

where

.. code-block:: text

X = [0|1|2|3|4|5|6|7|8|9].
```

- Sections: The MPS file consists of several sections where the names in capitals indicate the beginning of a new section. For example, COLUMNS denotes the beginning of the columns section.
- Comments: Lines starting with an * are comment lines and are ignored by MOSEK.
- Keys: The question marks represent keys to be specified later.
- Extensions: The sections QSECTION and CSECTION are specific MOSEK extensions of the MPS format. The sections QMATRIX, QUADOBJ and QCMATRIX are included for sake of compatibility with other vendors extensions to the MPS format.

The standard MPS format is a fixed format, i.e. everything in the MPS file must be within certain fixed positions. **MOSEK** also supports a *free format*. See Section 14.2.9 for details.

Linear example lo1.mps

A concrete example of a MPS file is presented below:

```
* File: lo1.mps
NAME lo1
OBJSENSE

EMD!	HIH		

Subsequently each individual section in the MPS format is discussed.

Section NAME

In this section a name ([name]) is assigned to the problem.

OBJSENSE (optional)

This is an optional section that can be used to specify the sense of the objective function. The OBJSENSE section contains one line at most which can be one of the following

```
MIN
MINIMIZE
MAX
MAXIMIZE
```

It should be obvious what the implication is of each of these four lines.

OBJNAME (optional)

This is an optional section that can be used to specify the name of the row that is used as objective function. The <code>OBJNAME</code> section contains one line at most which has the form

```
objname
```

objname should be a valid row name.

ROWS

A record in the ROWS section has the form

```
? [cname1]
```

where the requirements for the fields are as follows:

Field	Starting Position	Max Width	required	Description
?	2	1	Yes	Constraint key
[cname1]	5	8	Yes	Constraint name

Hence, in this section each constraint is assigned an unique name denoted by [cname1]. Please note that [cname1] starts in position 5 and the field can be at most 8 characters wide. An initial key ? must be present to specify the type of the constraint. The key can have the values E, G, L, or N with the following interpretation:

Constraint type	l_i^c	u_i^c
E	finite	l_i^c
G	finite	∞
L	$-\infty$	finite
N	$-\infty$	∞

In the MPS format an objective vector is not specified explicitly, but one of the constraints having the key N will be used as the objective vector c. In general, if multiple N type constraints are specified, then the first will be used as the objective vector c.

COLUMNS

In this section the elements of A are specified using one or more records having the form:

[vname1]	[cname1]	[value1]	[cname2]	[value2]

where the requirements for each field are as follows:

Field	Starting Position	Max Width	required	Description
[vname1]	5	8	Yes	Variable name
[cname1]	15	8	Yes	Constraint name
[value1]	25	12	Yes	Numerical value
[cname2]	40	8	No	Constraint name
[value2]	50	12	No	Numerical value

Hence, a record specifies one or two elements a_{ij} of A using the principle that [vname1] and [cname1] determines j and i respectively. Please note that [cname1] must be a constraint name specified in the ROWS section. Finally, [value1] denotes the numerical value of a_{ij} . Another optional element is specified by [cname2], and [value2] for the variable specified by [vname1]. Some important comments are:

- All elements belonging to one variable must be grouped together.
- Zero elements of A should not be specified.
- At least one element for each variable should be specified.

RHS (optional)

A record in this section has the format

[name] [cname1] [value1] [cname2] [value2]	
--	--

where the requirements for each field are as follows:

Field	Starting Position	Max Width	required	Description
[name]	5	8	Yes	Name of the RHS vector
[cname1]	15	8	Yes	Constraint name
[value1]	25	12	Yes	Numerical value
[cname2]	40	8	No	Constraint name
[value2]	50	12	No	Numerical value

The interpretation of a record is that [name] is the name of the RHS vector to be specified. In general, several vectors can be specified. [cname1] denotes a constraint name previously specified in the ROWS section. Now, assume that this name has been assigned to the i th constraint and v_1 denotes the value specified by [value1], then the interpretation of v_1 is:

Constraint	l_i^c	u_i^c
type		
E	v_1	v_1
G	v_1	
L		v_1
N		

An optional second element is specified by [cname2] and [value2] and is interpreted in the same way. Please note that it is not necessary to specify zero elements, because elements are assumed to be zero.

RANGES (optional)

A record in this section has the form

|--|--|--|

where the requirements for each fields are as follows:

Field	Starting Position	Max Width	required	Description
[name]	5	8	Yes	Name of the RANGE vector
[cname1]	15	8	Yes	Constraint name
[value1]	25	12	Yes	Numerical value
[cname2]	40	8	No	Constraint name
[value2]	50	12	No	Numerical value

The records in this section are used to modify the bound vectors for the constraints, i.e. the values in l^c and u^c . A record has the following interpretation: [name] is the name of the RANGE vector and [cname1] is a valid constraint name. Assume that [cname1] is assigned to the i th constraint and let v_1 be the value specified by [value1], then a record has the interpretation:

Constraint type	Sign of v_1	l_i^c	u_i^c
E	_	$u_i^c + v_1$	
E	+		$l_i^c + v_1$
G	- or +	$l_i^c + v_1 $	
L	- or +	$u_i^c - v_1 $	
N			

QSECTION (optional)

Within the QSECTION the label [cname1] must be a constraint name previously specified in the ROWS section. The label [cname1] denotes the constraint to which the quadratic term belongs. A record in the QSECTION has the form

[vname1] [vname2] [value1] [vname3	[value2]
------------------------------------	----------

where the requirements for each field are:

Field	Starting Position	Max Width	required	Description
[vname1]	5	8	Yes	Variable name
[vname2]	15	8	Yes	Variable name
[value1]	25	12	Yes	Numerical value
[vname3]	40	8	No	Variable name
[value2]	50	12	No	Numerical value

A record specifies one or two elements in the lower triangular part of the Q^i matrix where [cname1] specifies the i. Hence, if the names [vname1] and [vname2] have been assigned to the k th and j th variable, then Q^i_{kj} is assigned the value given by [value1] An optional second element is specified in the same way by the fields [vname1], [vname3], and [value2].

The example

minimize
$$-x_2 + \frac{1}{2}(2x_1^2 - 2x_1x_3 + 0.2x_2^2 + 2x_3^2)$$
 subject to
$$x_1 + x_2 + x_3 \geq 0$$

$$\geq 1,$$

has the following MPS file representation

```
* File: qo1.mps
NAME
ROWS
N obj
G c1
COLUMNS
           c1
x1
                      1.0

                      2.0
x1
           x1
x1
           xЗ
                      -1.0
x2
           x2
                      0.2
хЗ
           xЗ
                      2.0
ENDATA
```

Regarding the QSECTIONs please note that:

- Only one QSECTION is allowed for each constraint.
- The QSECTIONs can appear in an arbitrary order after the COLUMNS section.
- All variable names occurring in the QSECTION must already be specified in the COLUMNS section.
- ullet All entries specified in a QSECTION are assumed to belong to the lower triangular part of the quadratic term of Q.

QMATRIX/QUADOBJ (optional)

The QMATRIX and QUADOBJ sections allow to define the quadratic term of the objective function. They differ in how the quadratic term of the objective function is stored:

- ullet QMATRIX It stores all the nonzeros coefficients, without taking advantage of the symmetry of the Q matrix.
- QUADOBJ It only store the upper diagonal nonzero elements of the Q matrix.

A record in both sections has the form:

where the requirements for each field are:

Field	Starting Position	Max Width	required	Description
[vname1]	5	8	Yes	Variable name
[vname2]	15	8	Yes	Variable name
[value1]	25	12	Yes	Numerical value

A record specifies one elements of the Q matrix in the objective function. Hence, if the names [vname1] and [vname2] have been assigned to the k th and j th variable, then Q_{kj} is assigned the value given by [value1]. Note that a line must apper for each off-diagonal coefficient if using a QMATRIX section, while only one entry is required in a QUADOBJ section. The quadratic part of the objective function will be evaluated as $1/2x^TQx$.

The example

$$\begin{array}{ll} \text{minimize} & -x_2 + \frac{1}{2}(2x_1^2 - 2x_1x_3 + 0.2x_2^2 + 2x_3^2) \\ \text{subject to} & x_1 + x_2 + x_3 & \geq & 1, \\ & x \geq 0 & \end{array}$$

has the following MPS file representation using QMATRIX

```

                         0.2
    x2
              x2
    x3
              xЗ
                         2.0
ENDATA
```

Please also note that:

- A QMATRIX/QUADOBJ section can appear in an arbitrary order after the COLUMNS section.
- ullet All variable names occurring in the QMATRIX/QUADOBJ section must already be specified in the COLUMNS section.

14.2.2 QCMATRIX (optional)

A QCMATRIX section allows to specify the quadratic part of a given constraints. Within the QCMATRIX the label [cname1] must be a constraint name previously specified in the ROWS section. The label [cname1] denotes the constraint to which the quadratic term belongs. A record in the QSECTION has the form

where the requirements for each field are:

Field	Starting Position	Max Width	required	Description
[vname1]	5	8	Yes	Variable name
[vname2]	15	8	Yes	Variable name
[value1]	25	12	Yes	Numerical value

A record specifies an entry of the Q^i matrix where [cname1] specifies the i. Hence, if the names [vname1] and [vname2] have been assigned to the k th and j th variable, then Q^i_{kj} is assigned the value given by [value1]. Moreover, the quadratic term is represented as $1/2x^TQx$.

The example

has the following MPS file representation

		qo1.mps		
NAM	E	q	o1	
ROW	S			
N	obj			
	c1			
	q1			
	UMNS			
	x1	C	1	1.0
	x2		- bj	-1.0
	x2	C		1.0
	x3	C:		1.0
RHS		C.	_	1.0
кпъ				4.0
	rhs			1.0
	rhs			10.0
QCM	ATRI			
	x1	x		2.0
	x1	X	3	-1.0
	xЗ	x	1	-1.0
	x2	x:	2	0.2
	xЗ	x	3	2.0
END				

Regarding the QCMATRIXs please note that:

- Only one QCMATRIX is allowed for each constraint.
- The QCMATRIXs can appear in an arbitrary order after the COLUMNS section.
- All variable names occurring in the QSECTION must already be specified in the COLUMNS section.
- A QCMATRIX does not exploit the symmetry of Q: an off-diagonal entry (i,j) should appear twice.

14.2.3 BOUNDS (optional)

In the BOUNDS section changes to the default bounds vectors l^x and u^x are specified. The default bounds vectors are $l^x=0$ and $u^x=\infty$. Moreover, it is possible to specify several sets of bound vectors. A

record in this section has the form

' [name] [vna	me1l [value1]
Litanic] [viia	morj [varacrj

where the requirements for each field are:

Field	Starting Position	Max Width	Required	Description
??	2	2	Yes	Bound key
[name]	5	8	Yes	Name of the BOUNDS vector
[vname1]	15	8	Yes	Variable name
[value1]	25	12	No	Numerical value

Hence, a record in the BOUNDS section has the following interpretation: [name] is the name of the bound vector and [vname1] is the name of the variable which bounds are modified by the record. ?? and [value1] are used to modify the bound vectors according to the following table:

??	l_j^x	u_j^x	Made integer (added to ${\mathcal J}$)
FR	$-\infty$	∞	No
FX	v_1	v_1	No
LO	v_1	unchanged	No
MI	$-\infty$	unchanged	No
PL	unchanged	∞	No
UP	unchanged	v_1	No
BV	0	1	Yes
LI	$\lceil v_1 \rceil$	unchanged	Yes
UI	unchanged	$\lfloor v_1 \rfloor$	Yes

v 1 is the value specified by [value1].

14.2.4 CSECTION (optional)

The purpose of the CSECTION is to specify the constraint

$$x \in \mathcal{K}$$
.

in (14.2). It is assumed that K satisfies the following requirements. Let

$$x^t \in \mathbb{R}^{n^t}, \quad t = 1, \dots, k$$

be vectors comprised of parts of the decision variables x so that each decision variable is a member of exactly **one** vector x^t , for example

$$x^1 = \begin{bmatrix} x_1 \\ x_4 \\ x_7 \end{bmatrix}$$
 and $x^2 = \begin{bmatrix} x_6 \\ x_5 \\ x_3 \\ x_2 \end{bmatrix}$.

Next define

$$\mathcal{K} := \left\{ x \in \mathbb{R}^n : \quad x^t \in \mathcal{K}_t, \quad t = 1, \dots, k \right\}$$

where \mathcal{K}_t must have one of the following forms

• \mathbb{R} set:

$$\mathcal{K}_t = \left\{ x \in \mathbb{R}^{n^t} \right\}.$$

• Quadratic cone:

$$\mathcal{K}_t = \left\{ x \in \mathbb{R}^{n^t} : x_1 \ge \sqrt{\sum_{j=2}^{n^t} x_j^2} \right\}. \tag{14.3}$$

• Rotated quadratic cone:

$$\mathcal{K}_t = \left\{ x \in \mathbb{R}^{n^t} : 2x_1 x_2 \ge \sum_{j=3}^{n^t} x_j^2, \quad x_1, x_2 \ge 0 \right\}.$$
 (14.4)

In general, only quadratic and rotated quadratic cones are specified in the MPS file whereas membership of the \mathbb{R} set is not. If a variable is not a member of any other cone then it is assumed to be a member of an \mathbb{R} cone.

Next, let us study an example. Assume that the quadratic cone

$$x_4 \ge \sqrt{x_5^2 + x_8^2}$$

and the rotated quadratic cone

$$x_3x_7 \ge x_1^2 + x_0^2, \quad x_3, x_7 \ge 0,$$

should be specified in the MPS file. One CSECTION is required for each cone and they are specified as follows:

*	1	2	3	4	5	6	
*2345678901234567890123456789012345678901234567890							
CSECTION	kone	ea	0.0	QUAD			
x4							
x5							
x8							
CSECTION	kone	eb	0.0	RQUAD			
x7							
x3							
x1							
x0							

This first CSECTION specifies the cone (14.3) which is given the name konea. This is a quadratic cone which is specified by the keyword QUAD in the CSECTION header. The 0.0 value in the CSECTION header is not used by the QUAD cone.

The second CSECTION specifies the rotated quadratic cone (14.4). Please note the keyword RQUAD in the CSECTION which is used to specify that the cone is a rotated quadratic cone instead of a quadratic cone. The 0.0 value in the CSECTION header is not used by the RQUAD cone.

In general, a CSECTION header has the format

where the requirement for each field are as follows:

Field	Starting Position	Max Width	Required	Description
[kname1]	5	8	Yes	Name of the cone
[value1]	15	12	No	Cone parameter
[ktype]	25		Yes	Type of the cone.

The possible cone type keys are:

Cone type key	Members	Interpretation.
QUAD	≤ 1	Quadratic cone i.e. (14.3).
RQUAD	≤ 2	Rotated quadratic cone i.e. (14.4).

Please note that a quadratic cone must have at least one member whereas a rotated quadratic cone must have at least two members. A record in the CSECTION has the format

[vname1]

where the requirements for each field are

Field	Starting Position	Max Width	required	Description
[vname1]	2	8	Yes	A valid variable name

The most important restriction with respect to the CSECTION is that a variable must occur in only one CSECTION.

14.2.5 ENDATA

This keyword denotes the end of the MPS file.

14.2.6 Integer Variables

Using special bound keys in the BOUNDS section it is possible to specify that some or all of the variables should be integer-constrained i.e. be members of \mathcal{J} . However, an alternative method is available.

This method is available only for backward compatibility and we recommend that it is not used. This method requires that markers are placed in the COLUMNS section as in the example:

COLUMNS				
x1	obj	-10.0	c1	0.7
x1	c2	0.5	c3	1.0
x1	c4	0.1		
* Start	of integer-	constrained var	riables.	
MARK000	'MARKER'		'INTORG'	
x2	obj	-9.0	c1	1.0
x2	c2	0.8333333333	c3	0.66666667
x2	c4	0.25		
x3	obj	1.0	c6	2.0
MARKO01	'MARKER'		'INTEND'	

• End of integer-constrained variables.

Please note that special marker lines are used to indicate the start and the end of the integer variables. Furthermore be aware of the following

- IMPORTANT: All variables between the markers are assigned a default lower bound of 0 and a default upper bound of 1. **This may not be what is intended.** If it is not intended, the correct bounds should be defined in the BOUNDS section of the MPS formatted file.
- MOSEK ignores field 1, i.e. MARKO001 and MARKO01, however, other optimization systems require
 them.
- Field 2, i.e. MARKER, must be specified including the single quotes. This implies that no row can be assigned the name MARKER.
- Field 3 is ignored and should be left blank.
- Field 4, i.e. INTORG and INTEND, must be specified.
- It is possible to specify several such integer marker sections within the COLUMNS section.

14.2.7 General Limitations

• An MPS file should be an ASCII file.

14.2.8 Interpretation of the MPS Format

Several issues related to the MPS format are not well-defined by the industry standard. However, **MOSEK** uses the following interpretation:

- If a matrix element in the COLUMNS section is specified multiple times, then the multiple entries are added together.
- If a matrix element in a QSECTION section is specified multiple times, then the multiple entries are added together.

14.2.9 The Free MPS Format

MOSEK supports a free format variation of the MPS format. The free format is similar to the MPS file format but less restrictive, e.g. it allows longer names. However, it also presents two main limitations:

• A name must not contain any blanks.

14.3 The OPF Format

The Optimization Problem Format (OPF) is an alternative to LP and MPS files for specifying optimization problems. It is row-oriented, inspired by the CPLEX LP format.

Apart from containing objective, constraints, bounds etc. it may contain complete or partial solutions, comments and extra information relevant for solving the problem. It is designed to be easily read and modified by hand and to be forward compatible with possible future extensions.

Intended use

The OPF file format is meant to replace several other files:

- The LP file format: Any problem that can be written as an LP file can be written as an OPF file too; furthermore it naturally accommodates ranged constraints and variables as well as arbitrary characters in names, fixed expressions in the objective, empty constraints, and conic constraints.
- Parameter files: It is possible to specify integer, double and string parameters along with the problem (or in a separate OPF file).
- Solution files: It is possible to store a full or a partial solution in an OPF file and later reload it.

14.3.1 The File Format

The format uses tags to structure data. A simple example with the basic sections may look like this:

```
[comment]
This is a comment. You may write almost anything here...
[/comment]

# This is a single-line comment.

[objective min 'myobj']
x + 3 y + x^2 + 3 y^2 + z + 1
[/objective]

[constraints]
[con 'con01'] 4 &<= x + y [/con]
[/constraints]</pre>
```

```
[bounds]
[b] -10 &<= x,y &<= 10 [/b]

[cone quad] x,y,z [/cone]
[/bounds]
```

A scope is opened by a tag of the form [tag] and closed by a tag of the form [/tag]. An opening tag may accept a list of unnamed and named arguments, for examples:

```
[tag value] tag with one unnamed argument [/tag]
[tag arg=value] tag with one named argument in quotes [/tag]
```

Unnamed arguments are identified by their order, while named arguments may appear in any order, but never before an unnamed argument. The value can be a quoted, single-quoted or double-quoted text string, i.e.

```
[tag 'value'] single-quoted value [/tag]
[tag arg='value'] single-quoted value [/tag]
[tag "value"] double-quoted value [/tag]
[tag arg="value"] double-quoted value [/tag]
```

Sections

The recognized tags are

[comment]

A comment section. This can contain *almost* any text: Between single quotes (') or double quotes (") any text may appear. Outside quotes the markup characters ([and]) must be prefixed by backslashes. Both single and double quotes may appear alone or inside a pair of quotes if it is prefixed by a backslash.

[objective]

The objective function: This accepts one or two parameters, where the first one (in the above example min) is either min or max (regardless of case) and defines the objective sense, and the second one (above myobj), if present, is the objective name. The section may contain linear and quadratic expressions. If several objectives are specified, all but the last are ignored.

[constraints]

This does not directly contain any data, but may contain the subsection con defining a linear constraint.

[con] defines a single constraint; if an argument is present ([con NAME]) this is used as the name of the constraint, otherwise it is given a null-name. The section contains a constraint definition written as linear and quadratic expressions with a lower bound, an upper bound, with both or with an equality. Examples:

Constraint names are unique. If a constraint is specified which has the same name as a previously defined constraint, the new constraint replaces the existing one.

[bounds]

This does not directly contain any data, but may contain the subsections b (linear bounds on variables) and cone (quadratic cone).

[b]. Bound definition on one or several variables separated by comma (,). An upper or lower bound on a variable replaces any earlier defined bound on that variable. If only one bound (upper or lower) is given only this bound is replaced. This means that upper and lower bounds can be specified separately. So the OPF bound definition:

```
[b] x,y >= -10 [/b]
[b] x,y <= 10 [/b]
```

results in the bound $-10 \le x, y \le 10$.

[cone]. currently supports the quadratic cone and the rotated quadratic cone.

A conic constraint is defined as a set of variables which belong to a single unique cone.

• A quadratic cone of n variables x_1, \ldots, x_n defines a constraint of the form

$$x_1^2 > \sum_{i=2}^n x_i^2.$$

• A rotated quadratic cone of n variables x_1, \ldots, x_n defines a constraint of the form

$$x_1 x_2 > \sum_{i=3}^{n} x_i^2.$$

A [bounds]-section example:

By default all variables are free.

[variables]

This defines an ordering of variables as they should appear in the problem. This is simply a space-separated list of variable names.

[integer]

This contains a space-separated list of variables and defines the constraint that the listed variables must be integer values.

[hints]

This may contain only non-essential data; for example estimates of the number of variables, constraints and non-zeros. Placed before all other sections containing data this may reduce the time spent reading the file.

In the hints section, any subsection which is not recognized by MOSEK is simply ignored. In this section a hint in a subsection is defined as follows:

```
[hint ITEM] value [/hint]
```

where ITEM may be replaced by numvar (number of variables), numcon (number of linear/quadratic constraints), numanz (number of linear non-zeros in constraints) and numqnz (number of quadratic non-zeros in constraints).

[solutions]

This section can contain a set of full or partial solutions to a problem. Each solution must be specified using a [solution]-section, i.e.

```
[solutions]
[solution]...[/solution] #solution 1
[solution]...[/solution] #solution 2
#other solutions....
[solution]...[/solution] #solution n
[/solutions]
```

Note that a [solution]-section must be always specified inside a [solutions]-section. The syntax of a [solution]-section is the following:

```
[solution SOLTYPE status=STATUS]...[/solution]
```

where SOLTYPE is one of the strings

- interior, a non-basic solution,
- basic, a basic solution,
- integer, an integer solution,

and STATUS is one of the strings

- UNKNOWN,
- OPTIMAL,
- INTEGER_OPTIMAL,
- PRIM_FEAS,
- DUAL_FEAS,
- PRIM_AND_DUAL_FEAS,
- NEAR_OPTIMAL,
- NEAR_PRIM_FEAS,
- NEAR_DUAL_FEAS,
- NEAR_PRIM_AND_DUAL_FEAS,
- PRIM_INFEAS_CER,
- DUAL_INFEAS_CER,
- NEAR_PRIM_INFEAS_CER,

- NEAR_DUAL_INFEAS_CER,
- NEAR_INTEGER_OPTIMAL.

Most of these values are irrelevant for input solutions; when constructing a solution for simplex hot-start or an initial solution for a mixed integer problem the safe setting is UNKNOWN.

A [solution]-section contains [con] and [var] sections. Each [con] and [var] section defines solution information for a single variable or constraint, specified as list of KEYWORD/value pairs, in any order, written as

KEYWORD=value

Allowed keywords are as follows:

- sk. The status of the item, where the value is one of the following strings:
 - LOW, the item is on its lower bound.
 - UPR, the item is on its upper bound.
 - FIX, it is a fixed item.
 - BAS, the item is in the basis.
 - SUPBAS, the item is super basic.
 - UNK, the status is unknown.
 - INF, the item is outside its bounds (infeasible).
- 1vl Defines the level of the item.
- s1 Defines the level of the dual variable associated with its lower bound.
- su Defines the level of the dual variable associated with its upper bound.
- sn Defines the level of the variable associated with its cone.
- y Defines the level of the corresponding dual variable (for constraints only).

A [var] section should always contain the items sk, lvl, sl and su. Items sl and su are not required for integer solutions.

A [con] section should always contain sk, lvl, sl, su and y.

An example of a solution section

• [vendor] This contains solver/vendor specific data. It accepts one argument, which is a vendor ID – for MOSEK the ID is simply mosek – and the section contains the subsection parameters defining solver parameters. When reading a vendor section, any unknown vendor can be safely ignored. This is described later.

Comments using the # may appear anywhere in the file. Between the # and the following line-break any text may be written, including markup characters.

Numbers

Numbers, when used for parameter values or coefficients, are written in the usual way by the printf function. That is, they may be prefixed by a sign (+ or -) and may contain an integer part, decimal part and an exponent. The decimal point is always . (a dot). Some examples are

```
1
1.0
.0
.0
1.
1e10
1e+10
1e-10
```

Some invalid examples are

```
e10 # invalid, must contain either integer or decimal part
. # invalid
.e10 # invalid
```

More formally, the following standard regular expression describes numbers as used:

```
[+|-]?([0-9]+[.][0-9]*|[.][0-9]+)([eE][+|-]?[0-9]+)?
```

Names

Variable names, constraint names and objective name may contain arbitrary characters, which in some cases must be enclosed by quotes (single or double) that in turn must be preceded by a backslash. Unquoted names must begin with a letter (a-z or A-Z) and contain only the following characters: the letters a-z and A-Z, the digits 0-9, braces ({ and }) and underscore (_).

Some examples of legal names:

```
an_unquoted_name
another_name{123}
'single quoted name'
"double quoted name"
"name with \\"quote\\" in it"
"name with []s in it"
```

14.3.2 Parameters Section

In the vendor section solver parameters are defined inside the parameters subsection. Each parameter is written as

```
[p PARAMETER_NAME] value [/p]
```

where PARAMETER_NAME is replaced by a MOSEK parameter name, usually of the form MSK_IPAR_..., MSK_DPAR_... or MSK_SPAR_..., and the value is replaced by the value of that parameter; both integer values and named values may be used. Some simple examples are

14.3.3 Writing OPF Files from MOSEK

To write an OPF file add the .opf extension to the file name.

14.3.4 Examples

This section contains a set of small examples written in OPF and describing how to formulate linear, quadratic and conic problems.

Linear Example 1o1.opf

Consider the example:

having the bounds

$$\begin{array}{cccccc} 0 & \leq & x_0 & \leq & \infty, \\ 0 & \leq & x_1 & \leq & 10, \\ 0 & \leq & x_2 & \leq & \infty, \\ 0 & \leq & x_3 & \leq & \infty. \end{array}$$

In the OPF format the example is displayed as shown in Listing 14.1.

Listing 14.1: Example of an OPF file for a linear problem.

```
[comment]

[/comment]
[hints]
  [hint NUMVAR] 4 [/hint]
  [hint NUMCON] 3 [/hint]
  [hint NUMANZ] 9 [/hint]
[/hints]
[variables disallow_new_variables]
 x1 x2 x3 x4
[/variables]
[objective maximize 'obj']
  3 x1 + x2 + 5 x3 + x4
[/objective]
[constraints]
  [con 'c1'] 3 x1 + x2 + 2 x3 = 30 [/con]
 [con 'c2'] 2 x1 + x2 + 3 x3 + x4 >= 15 [/con]
  [con 'c3'] 2 x2 + 3 x4 \le 25 [/con]
[/constraints]
  [b] 0 <= * [/b]
  [b] 0 \le x2 \le 10 [/b]
[/bounds]
```

Quadratic Example qo1.opf

An example of a quadratic optimization problem is

minimize
$$x_1^2 + 0.1x_2^2 + x_3^2 - x_1x_3 - x_2$$

subject to $1 \le x_1 + x_2 + x_3, x > 0.$

This can be formulated in opf as shown below.

Listing 14.2: Example of an OPF file for a quadratic problem.

```
[comment]
 The qo1 example in OPF format
[/comment]
[hints]
 [hint NUMVAR] 3 [/hint]
 [hint NUMCON] 1 [/hint]
 [hint NUMANZ] 3 [/hint]
 [hint NUMQNZ] 4 [/hint]
[/hints]
[variables disallow_new_variables]
 x1 x2 x3
[/variables]
[objective minimize 'obj']
 # The quadratic terms are often written with a factor of 1/2 as here,
 # but this is not required.
  - x2 + 0.5 ( 2.0 x1 ^ 2 - 2.0 x3 * x1 + 0.2 x2 ^ 2 + 2.0 x3 ^ 2 )
[/objective]
[constraints]
 [con 'c1'] 1.0 <= x1 + x2 + x3 [/con]
[/constraints]
[bounds]
 [b] 0 <= * [/b]
[/bounds]
```

Conic Quadratic Example cqo1.opf

Consider the example:

$$\begin{array}{lll} \text{minimize} & x_3 + x_4 + x_5 \\ \text{subject to} & x_0 + x_1 + 2x_2 & = & 1, \\ & x_0, x_1, x_2 & \geq & 0, \\ & x_3 \geq \sqrt{x_0^2 + x_1^2}, & \\ & 2x_4x_5 \geq x_2^2. & \end{array}$$

Please note that the type of the cones is defined by the parameter to [cone ...]; the content of the cone-section is the names of variables that belong to the cone. The resulting OPF file is in Listing 14.3.

Listing 14.3: Example of an OPF file for a conic quadratic problem.

```
[comment]
  The cqo1 example in OPF format.
[/comment]
[hints]
```

```
[hint NUMVAR] 6 [/hint]
  [hint NUMCON] 1 [/hint]
  [hint NUMANZ] 3 [/hint]
[/hints]
[variables disallow_new_variables]
 x1 x2 x3 x4 x5 x6
[/variables]
[objective minimize 'obj']
  x4 + x5 + x6
[/objective]
[constraints]
 [con 'c1'] x1 + x2 + 2e+00 x3 = 1e+00 [/con]
[/constraints]
[bounds]
 # We let all variables default to the positive orthant
  [b] 0 <= * [/b]
  # ...and change those that differ from the default
  [b] x4,x5,x6 free [/b]
  # Define quadratic cone: x4 \ge sqrt(x1^2 + x2^2)
  [cone quad 'k1'] x4, x1, x2 [/cone]
  # Define rotated quadratic cone: 2 x5 x6 >= x3^2
  [cone rquad 'k2'] x5, x6, x3 [/cone]
[/bounds]
```

Mixed Integer Example milo1.opf

Consider the mixed integer problem:

This can be implemented in OPF with the file in Listing 14.4.

Listing 14.4: Example of an OPF file for a mixed-integer linear problem.

```
[comment]
  The milo1 example in OPF format
[/comment]

[hints]
  [hint NUMVAR] 2 [/hint]
  [hint NUMCON] 2 [/hint]
  [hint NUMANZ] 4 [/hint]
[/hints]

[variables disallow_new_variables]
  x1 x2
[/variables]

[objective maximize 'obj']
  x1 + 6.4e-1 x2
[/objective]
```

```
[constraints]
  [con 'c1'] 5e+1 x1 + 3.1e+1 x2 <= 2.5e+2 [/con]
  [con 'c2'] -4 <= 3 x1 - 2 x2 [/con]
[/constraints]

[bounds]
  [b] 0 <= * [/b]
[/bounds]

[integer]
  x1 x2
[/integer]</pre>
```

14.4 The CBF Format

This document constitutes the technical reference manual of the *Conic Benchmark Format* with file extension: .cbf or .CBF. It unifies linear, second-order cone (also known as conic quadratic) and semidefinite optimization with mixed-integer variables. The format has been designed with benchmark libraries in mind, and therefore focuses on compact and easily parsable representations. The problem structure is separated from the problem data, and the format moreover facilitates benchmarking of hotstart capability through sequences of changes.

14.4.1 How Instances Are Specified

This section defines the spectrum of conic optimization problems that can be formulated in terms of the keywords of the CBF format.

In the CBF format, conic optimization problems are considered in the following form:

$$\min / \max \quad g^{obj}
g_i \in \mathcal{K}_i, \quad i \in \mathcal{I},
\text{s.t.} \quad G_i \in \mathcal{K}_i, \quad i \in \mathcal{I}^{PSD},
x_j \in \mathcal{K}_j, \quad j \in \mathcal{J},
\overline{X}_j \in \mathcal{K}_j, \quad j \in \mathcal{J}^{PSD}.$$
(14.5)

- Variables are either scalar variables, x_j for $j \in \mathcal{J}$, or variables, \overline{X}_j for $j \in \mathcal{J}^{PSD}$. Scalar variables can also be declared as integer.
- Constraints are affine expressions of the variables, either scalar-valued g_i for $i \in \mathcal{I}$, or matrix-valued G_i for $i \in \mathcal{I}^{PSD}$

$$g_i = \sum_{j \in \mathcal{J}^{PSD}} \langle F_{ij}, X_j \rangle + \sum_{j \in \mathcal{J}} a_{ij} x_j + b_i,$$
$$G_i = \sum_{j \in \mathcal{J}} x_j H_{ij} + D_i.$$

• The **objective function** is a scalar-valued affine expression of the variables, either to be minimized or maximized. We refer to this expression as g^{obj}

$$g^{obj} = \sum_{j \in \mathcal{J}^{PSD}} \langle F_j^{obj}, X_j \rangle + \sum_{j \in \mathcal{J}} a_j^{obj} x_j + b^{obj}.$$

CBF format can represent the following cones \mathcal{K} :

• Free domain - A cone in the linear family defined by

$$\{x \in \mathbb{R}^n\}$$
, for $n \ge 1$.

14.4. The CBF Format

• Positive orthant - A cone in the linear family defined by

$$\{x \in \mathbb{R}^n \mid x_j \ge 0 \text{ for } j = 1, \dots, n\}, \text{ for } n \ge 1.$$

• Negative orthant - A cone in the linear family defined by

$$\{x \in \mathbb{R}^n \mid x_i \leq 0 \text{ for } j = 1, \dots, n\}, \text{ for } n \geq 1.$$

• Fixpoint zero - A cone in the linear family defined by

$$\{x \in \mathbb{R}^n \mid x_j = 0 \text{ for } j = 1, \dots, n\}, \text{ for } n \ge 1.$$

• Quadratic cone - A cone in the second-order cone family defined by

$$\left\{ \left(\begin{array}{c} p \\ x \end{array}\right) \in \mathbb{R} \times \mathbb{R}^{n-1}, \ p^2 \ge x^T x, \ p \ge 0 \right\}, \ \text{for } n \ge 2.$$

• Rotated quadratic cone - A cone in the second-order cone family defined by

$$\left\{ \begin{pmatrix} p \\ q \\ x \end{pmatrix} \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^{n-2}, \ 2pq \ge x^T x, \ p \ge 0, \ q \ge 0 \right\}, \text{ for } n \ge 3.$$

14.4.2 The Structure of CBF Files

This section defines how information is written in the CBF format, without being specific about the type of information being communicated.

All information items belong to exactly one of the three groups of information. These information groups, and the order they must appear in, are:

- 1. File format.
- 2. Problem structure.
- 3. Problem data.

The first group, file format, provides information on how to interpret the file. The second group, problem structure, provides the information needed to deduce the type and size of the problem instance. Finally, the third group, problem data, specifies the coefficients and constants of the problem instance.

Information items

The format is composed as a list of information items. The first line of an information item is the KEYWORD, revealing the type of information provided. The second line - of some keywords only - is the HEADER, typically revealing the size of information that follows. The remaining lines are the BODY holding the actual information to be specified.

The KEYWORD determines how each line in the HEADER and BODY is structured. Moreover, the number of lines in the BODY follows either from the KEYWORD, the HEADER, or from another information item required to precede it.

Embedded hotstart-sequences

A sequence of problem instances, based on the same problem structure, is within a single file. This is facilitated via the CHANGE within the problem data information group, as a separator between the information items of each instance. The information items following a CHANGE keyword are appending to, or changing (e.g., setting coefficients back to their default value of zero), the problem data of the preceding instance.

The sequence is intended for benchmarking of hotstart capability, where the solvers can reuse their internal state and solution (subject to the achieved accuracy) as warmpoint for the succeeding instance. Whenever this feature is unsupported or undesired, the keyword CHANGE should be interpreted as the end of file.

File encoding and line width restrictions

The format is based on the US-ASCII printable character set with two extensions as listed below. Note, by definition, that none of these extensions can be misinterpreted as printable US-ASCII characters:

- A line feed marks the end of a line, carriage returns are ignored.
- Comment-lines may contain unicode characters in UTF-8 encoding.

The line width is restricted to 512 bytes, with 3 bytes reserved for the potential carriage return, line feed and null-terminator.

Integers and floating point numbers must follow the ISO C decimal string representation in the standard C locale. The format does not impose restrictions on the magnitude of, or number of significant digits in numeric data, but the use of 64-bit integers and 64-bit IEEE 754 floating point numbers should be sufficient to avoid loss of precision.

Comment-line and whitespace rules

The format allows single-line comments respecting the following rule:

• Lines having first byte equal to '#' (US-ASCII 35) are comments, and should be ignored. Comments are only allowed between information items.

Given that a line is not a comment-line, whitespace characters should be handled according to the following rules:

- Leading and trailing whitespace characters should be ignored.
 - The seperator between multiple pieces of information on one line, is either one or more whitespace characters.
- Lines containing only whitespace characters are empty, and should be ignored. Empty lines are only allowed between information items.

14.4.3 Problem Specification

The problem structure

The problem structure defines the objective sense, whether it is minimization and maximization. It also defines the index sets, \mathcal{J} , \mathcal{J}^{PSD} , \mathcal{I} and \mathcal{I}^{PSD} , which are all numbered from zero, $\{0, 1, \ldots\}$, and empty until explicitly constructed.

• Scalar variables are constructed in vectors restricted to a conic domain, such as $(x_0, x_1) \in \mathbb{R}^2_+$, $(x_2, x_3, x_4) \in \mathcal{Q}^3$, etc. In terms of the Cartesian product, this generalizes to

$$x \in \mathcal{K}_1^{n_1} \times \mathcal{K}_2^{n_2} \times \dots \times \mathcal{K}_k^{n_k}$$

which in the CBF format becomes:

```
VAR
n k
K1 n1
K2 n2
...
Kk nk
```

where $\sum_{i} n_{i} = n$ is the total number of scalar variables. The list of supported cones is found in Table 14.3. Integrality of scalar variables can be specified afterwards.

• **PSD variables** are constructed one-by-one. That is, $X_j \succeq \mathbf{0}^{n_j \times n_j}$ for $j \in \mathcal{J}^{PSD}$, constructs a matrix-valued variable of size $n_j \times n_j$ restricted to be symmetric positive semidefinite. In the CBF format, this list of constructions becomes:

```
PSDVAR
N
n1
n2
...
nN
```

where N is the total number of PSD variables.

• Scalar constraints are constructed in vectors restricted to a conic domain, such as $(g_0, g_1) \in \mathbb{R}^2_+$, $(g_2, g_3, g_4) \in \mathcal{Q}^3$, etc. In terms of the Cartesian product, this generalizes to

$$g \in \mathcal{K}_1^{m_1} \times \mathcal{K}_2^{m_2} \times \dots \times \mathcal{K}_k^{m_k}$$

which in the CBF format becomes:

```
CON
m k
K1 m1
K2 m2
..
Kk mk
```

where $\sum_{i} m_{i} = m$ is the total number of scalar constraints. The list of supported cones is found in Table 14.3.

• **PSD constraints** are constructed one-by-one. That is, $G_i \succeq \mathbf{0}^{m_i \times m_i}$ for $i \in \mathcal{I}^{PSD}$, constructs a matrix-valued affine expressions of size $m_i \times m_i$ restricted to be symmetric positive semidefinite. In the CBF format, this list of constructions becomes

```
PSDCON
M
m1
```

m2	
mM	

where M is the total number of PSD constraints.

With the objective sense, variables (with integer indications) and constraints, the definitions of the many affine expressions follow in problem data.

Problem data

The problem data defines the coefficients and constants of the affine expressions of the problem instance. These are considered zero until explicitly defined, implying that instances with no keywords from this information group are, in fact, valid. Duplicating or conflicting information is a failure to comply with the standard. Consequently, two coefficients written to the same position in a matrix (or to transposed positions in a symmetric matrix) is an error.

The affine expressions of the objective, g^{obj} , of the scalar constraints, g_i , and of the PSD constraints, G_i , are defined separately. The following notation uses the standard trace inner product for matrices, $\langle X, Y \rangle = \sum_{i,j} X_{ij} Y_{ij}$.

• The affine expression of the objective is defined as

$$g^{obj} = \sum_{j \in \mathcal{J}^{PSD}} \langle F_j^{obj}, X_j \rangle + \sum_{j \in \mathcal{J}} a_j^{obj} x_j + b^{obj},$$

in terms of the symmetric matrices, F_j^{obj} , and scalars, a_j^{obj} and b^{obj} .

• The affine expressions of the scalar constraints are defined, for $i \in \mathcal{I}$, as

$$g_i = \sum_{j \in \mathcal{J}^{PSD}} \langle F_{ij}, X_j \rangle + \sum_{j \in \mathcal{J}} a_{ij} x_j + b_i,$$

in terms of the symmetric matrices, F_{ij} , and scalars, a_{ij} and b_i .

• The affine expressions of the PSD constraints are defined, for $i \in \mathcal{I}^{PSD}$, as

$$G_i = \sum_{j \in \mathcal{J}} x_j H_{ij} + D_i,$$

in terms of the symmetric matrices, H_{ij} and D_i .

List of cones

The format uses an explicit syntax for symmetric positive semidefinite cones as shown above. For scalar variables and constraints, constructed in vectors, the supported conic domains and their minimum sizes are given as follows.

Table 14.3: Cones available in the CBF format

Name	CBF keyword	Cone family
Free domain	F	linear
Positive orthant	L+	linear
Negative orthant	L-	linear
Fixpoint zero	L=	linear
Quadratic cone	Q	second-order
Rotated quadratic cone	QR	second-order

14.4.4 File Format Keywords

VER

Description: The version of the Conic Benchmark Format used to write the file.

HEADER: None

BODY: One line formatted as:

INT

This is the version number.

Must appear exactly once in a file, as the first keyword.

OBJSENSE

Description: Define the objective sense.

HEADER: None

BODY: One line formatted as:

STR

having MIN indicates minimize, and MAX indicates maximize. Capital letters are required.

Must appear exactly once in a file.

PSDVAR

Description: Construct the PSD variables.

HEADER: One line formatted as:

INT

This is the number of PSD variables in the problem.

BODY: A list of lines formatted as:

INT

This indicates the number of rows (equal to the number of columns) in the matrix-valued PSD variable. The number of lines should match the number stated in the header.

VAR

Description: Construct the scalar variables.

HEADER: One line formatted as:

INT INT

This is the number of scalar variables, followed by the number of conic domains they are restricted to.

BODY: A list of lines formatted as:

STR INT

This indicates the cone name (see Table 14.3), and the number of scalar variables restricted to this cone. These numbers should add up to the number of scalar variables stated first in the header. The number of lines should match the second number stated in the header.

INT

Description: Declare integer requirements on a selected subset of scalar variables.

HEADER: one line formatted as:

INT

This is the number of integer scalar variables in the problem.

BODY: a list of lines formatted as:

INT

This indicates the scalar variable index $j \in \mathcal{J}$. The number of lines should match the number stated in the header.

Can only be used after the keyword VAR.

PSDCON

Description: Construct the PSD constraints.

HEADER: One line formatted as:

INT

This is the number of PSD constraints in the problem.

BODY: A list of lines formatted as:

INT

This indicates the number of rows (equal to the number of columns) in the matrix-valued affine expression of the PSD constraint. The number of lines should match the number stated in the header.

Can only be used after these keywords: PSDVAR, VAR.

CON

Description: Construct the scalar constraints.

HEADER: One line formatted as:

INT INT

This is the number of scalar constraints, followed by the number of conic domains they restrict to.

BODY: A list of lines formatted as:

STR INT

This indicates the cone name (see Table 14.3), and the number of affine expressions restricted to this cone. These numbers should add up to the number of scalar constraints stated first in the header. The number of lines should match the second number stated in the header.

Can only be used after these keywords: PSDVAR, VAR

OBJFCOORD

Description: Input sparse coordinates (quadruplets) to define the symmetric matrices F_j^{obj} , as used in the objective.

HEADER: One line formatted as:

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as:

INT INT INT REAL

This indicates the PSD variable index $j \in \mathcal{J}^{PSD}$, the row index, the column index and the coefficient value. The number of lines should match the number stated in the header.

OBJACOORD

Description: Input sparse coordinates (pairs) to define the scalars, a_i^{obj} , as used in the objective.

HEADER: One line formatted as:

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as:

INT REAL

This indicates the scalar variable index $j \in \mathcal{J}$ and the coefficient value. The number of lines should match the number stated in the header.

OBJBCOORD

Description: Input the scalar, b^{obj} , as used in the objective.

HEADER: None.

BODY: One line formatted as:

REAL

This indicates the coefficient value.

FCOORD

Description: Input sparse coordinates (quintuplets) to define the symmetric matrices, F_{ij} , as used in the scalar constraints.

HEADER: One line formatted as:

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as:

INT INT INT INT REAL

This indicates the scalar constraint index $i \in \mathcal{I}$, the PSD variable index $j \in \mathcal{J}^{PSD}$, the row index, the column index and the coefficient value. The number of lines should match the number stated in the header.

ACOORD

Description: Input sparse coordinates (triplets) to define the scalars, a_{ij} , as used in the scalar constraints.

HEADER: One line formatted as:

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as:

INT INT REAL

This indicates the scalar constraint index $i \in \mathcal{I}$, the scalar variable index $j \in \mathcal{J}$ and the coefficient value. The number of lines should match the number stated in the header.

BCOORD

Description: Input sparse coordinates (pairs) to define the scalars, b_i , as used in the scalar constraints.

HEADER: One line formatted as:

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as:

INT REAL

This indicates the scalar constraint index $i \in \mathcal{I}$ and the coefficient value. The number of lines should match the number stated in the header.

HCOORD

Description: Input sparse coordinates (quintuplets) to define the symmetric matrices, H_{ij} , as used in the PSD constraints.

HEADER: One line formatted as:

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as

INT INT INT INT REAL

This indicates the PSD constraint index $i \in \mathcal{I}^{PSD}$, the scalar variable index $j \in \mathcal{J}$, the row index, the column index and the coefficient value. The number of lines should match the number stated in the header.

DCOORD

Description: Input sparse coordinates (quadruplets) to define the symmetric matrices, D_i , as used in the PSD constraints.

HEADER: One line formatted as

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as:

INT INT INT REAL

This indicates the PSD constraint index $i \in \mathcal{I}^{PSD}$, the row index, the column index and the coefficient value. The number of lines should match the number stated in the header.

CHANGE

Start of a new instance specification based on changes to the previous. Can be interpreted as the end of file when the hotstart-sequence is unsupported or undesired.

BODY: None Header: None

14.4.5 CBF Format Examples

Minimal Working Example

The conic optimization problem (14.6), has three variables in a quadratic cone - first one is integer - and an affine expression in domain 0 (equality constraint).

minimize
$$5.1 x_0$$

subject to $6.2 x_1 + 7.3 x_2 - 8.4 \in \{0\}$
 $x \in \mathcal{Q}^3, x_0 \in \mathbb{Z}.$ (14.6)

Its formulation in the Conic Benchmark Format begins with the version of the CBF format used, to safeguard against later revisions.

VER 1

Next follows the problem structure, consisting of the objective sense, the number and domain of variables, the indices of integer variables, and the number and domain of scalar-valued affine expressions (i.e., the equality constraint).

This concludes the example.

Mixing Linear, Second-order and Semidefinite Cones

The conic optimization problem (14.7), has a semidefinite cone, a quadratic cone over unordered subindices, and two equality constraints.

The equality constraints are easily rewritten to the conic form, $(g_0, g_1) \in \{0\}^2$, by moving constants such that the right-hand-side becomes zero. The quadratic cone does not fit under the VAR keyword in this variable permutation. Instead, it takes a scalar constraint $(g_2, g_3, g_4) = (x_1, x_0, x_2) \in \mathcal{Q}^3$, with scalar variables constructed as $(x_0, x_1, x_2) \in \mathbb{R}^3$. Its formulation in the CBF format is reported in the following list

```

Mixing Semidefinite Variables and Linear Matrix Inequalities

The standard forms in semidefinite optimization are usually based either on semidefinite variables or linear matrix inequalities. In the CBF format, both forms are supported and can even be mixed as shown in.

minimize
$$\left\langle \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 1 \end{bmatrix}, X_1 \right\rangle + x_1 + x_2 + 1$$

subject to $\left\langle \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 0 \end{bmatrix}, X_1 \right\rangle - x_1 - x_2 \qquad \geq 0.0,$
 $x_1 \begin{bmatrix} 0 & 1 \\ 1 & 3 \end{bmatrix} + x_2 \begin{bmatrix} 3 & 1 \\ 1 & 0 \end{bmatrix} - \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \succeq \mathbf{0},$
 $X_1 \succeq \mathbf{0}.$ (14.8)

Its formulation in the CBF format is written in what follows

Optimization Over a Sequence of Objectives

The linear optimization problem (14.9), is defined for a sequence of objectives such that hotstarting from one to the next might be advantages.

$$\begin{array}{lll} \text{maximize}_k & g_k^{obj} \\ \text{subject to} & 50 \, x_0 + 31 & \leq & 250 \,, \\ & 3 \, x_0 - 2 x_1 & \geq & -4 \,, \\ & x \in \mathbb{R}^2_+, \end{array} \tag{14.9}$$

given,

$$\begin{aligned} &1. \ \ g_0^{obj} = x_0 + 0.64x_1. \\ &2. \ \ g_1^{obj} = 1.11x_0 + 0.76x_1. \end{aligned}$$

```
3. g_2^{obj} = 1.11x_0 + 0.85x_1.
```

Its formulation in the CBF format is reported in Listing 14.5.

Listing 14.5: Problem (14.9) in CBF format.

14.5 The XML (OSiL) Format

MOSEK can write data in the standard OSiL xml format. For a definition of the OSiL format please see http://www.optimizationservices.org/.

Only linear constraints (possibly with integer variables) are supported. By default output files with the extension .xml are written in the OSiL format.

14.6 The Task Format

The Task format is MOSEK's native binary format. It contains a complete image of a MOSEK task, i.e.

- Problem data: Linear, conic quadratic, semidefinite and quadratic data
- Problem item names: Variable names, constraints names, cone names etc.
- Parameter settings
- Solutions

There are a few things to be aware of:

- The task format *does not* support General Convex problems since these are defined by arbitrary user-defined functions.
- Status of a solution read from a file will always be unknown.

The format is based on the TAR (USTar) file format. This means that the individual pieces of data in a .task file can be examined by unpacking it as a TAR file. Please note that the inverse may not work: Creating a file using TAR will most probably not create a valid **MOSEK** Task file since the order of the entries is important.

14.7 The JSON Format

MOSEK provides the possibility to read/write problems in valid JSON format.

JSON (JavaScript Object Notation) is a lightweight data-interchange format. It is easy for humans to read and write. It is easy for machines to parse and generate. It is based on a subset of the JavaScript Programming Language, Standard ECMA-262 3rd Edition - December 1999. JSON is a text format that is completely language independent but uses conventions that are familiar to programmers of the C-family of languages, including C, C++, C#, Java, JavaScript, Perl, Python, and many others. These properties make JSON an ideal data-interchange language.

The official JSON website http://www.json.org provides plenty of information along with the format definition.

MOSEK defines two JSON-like formats:

- jtask
- jsol

Warning: Despite being text-based human-readable formats, *jtask* and *jsol* files will include no indentation and no new-lines, in order to keep the files as compact as possible. We therefore strongly advise to use JSON viewer tools to inspect *jtask* and *jsol* files.

14.7.1 jtask format

It stores a problem instance. The jtask format contains the same information as a task format.

Even though a jtask file is human-readable, we do not recommend users to create it by hand, but to rely on **MOSEK**.

14.7.2 jsol format

It stores a problem solution. The jsol format contains all solutions and information items.

14.7.3 A jtask example

In Listing 14.6 we present a file in the *jtask* format that corresponds to the sample problem from lol.lp. The listing has been formatted for readability.

Listing 14.6: A formatted *jtask* file for the lo1.lp example.

14.8 The Solution File Format

MOSEK provides several solution files depending on the problem type and the optimizer used:

- basis solution file (extension .bas) if the problem is optimized using the simplex optimizer or basis identification is performed,
- interior solution file (extension .sol) if a problem is optimized using the interior-point optimizer and no basis identification is required,
- integer solution file (extension .int) if the problem contains integer constrained variables.

All solution files have the format:

```
NAME
                    : <problem name>
                    : <status of the problem>
PROBLEM STATUS
SOLUTION STATUS
                   : <status of the solution>
OBJECTIVE NAME
                   : <name of the objective function>
PRIMAL OBJECTIVE
                  : <primal objective value corresponding to the solution>
DUAL OBJECTIVE
                    : <dual objective value corresponding to the solution>
CONSTRAINTS
INDEX NAME
                AT ACTIVITY
                               LOWER LIMIT
                                              UPPER LIMIT
                                                            DUAL LOWER
                                                                          DUAL UPPER
       <name>
               ?? <a value>
                               <a value>
                                              <a value>
                                                            <a value>
                                                                          <a value>

                                                                                        CONIC
\hookrightarrowDUAL
                ?? <a value>
                               <a value>
                                              <a value>
                                                             <a value>
                                                                          <a value>
       <name>
                                                                                        <a value>
```

In the example the fields ? and <> will be filled with problem and solution specific information. As can be observed a solution report consists of three sections, i.e.

- HEADER In this section, first the name of the problem is listed and afterwards the problem and solution status are shown. Next the primal and dual objective values are displayed.
- CONSTRAINTS For each constraint i of the form

$$l_i^c \le \sum_{j=1}^n a_{ij} x_j \le u_i^c, \tag{14.10}$$

the following information is listed:

- INDEX: A sequential index assigned to the constraint by MOSEK
- NAME: The name of the constraint assigned by the user.
- AT: The status of the constraint. In Table 14.4 the possible values of the status keys and their interpretation are shown.

Table 14.4: Status keys.

Status key	Interpretation
UN	Unknown status
BS	Is basic
SB	Is superbasic
LL	Is at the lower limit (bound)
UL	Is at the upper limit (bound)
EQ	Lower limit is identical to upper limit
**	Is infeasible i.e. the lower limit is greater than the upper limit.

- ACTIVITY: the quantity $\sum_{j=1}^n a_{ij} x_j^*$, where x^* is the value of the primal solution.
- LOWER LIMIT: the quantity l_i^c (see (14.10).)
- UPPER LIMIT: the quantity u_i^c (see (14.10).)
- DUAL LOWER: the dual multiplier corresponding to the lower limit on the constraint.
- DUAL UPPER: the dual multiplier corresponding to the upper limit on the constraint.
- VARIABLES The last section of the solution report lists information about the variables. This information has a similar interpretation as for the constraints. However, the column with the header CONIC DUAL is included for problems having one or more conic constraints. This column shows the dual variables corresponding to the conic constraints.

Example: lo1.sol

In Listing 14.7 we show the solution file for the lol.opf problem.

Listing 14.7: An example of .sol file.

INTERFACE CHANGES

The section show interface-specific changes to the **MOSEK** Fusion API for .NET in version 8. See the release notes for general changes and new features of the **MOSEK** Optimization Suite.

15.1 Compatibility

Fusion API has undergo a deep refactorization that will most likely make old code fail to compile. On a general level:

- more linear operators are avaible,
- pretty printing is implemented for most classes,
- variable operators (such slicingm stacking,...) are now moved to a specific class Var, pretty much like expressions have their own Expr.
- dimensions can now be expressed directly with arrays instead of the Set class
- reduced need for explicit conversion from variable to expression, i.e. the Variable.asExpr,
- new syntax to specify integer variables, as well as a short-hand for binary ones.

Compatibility guarantees for this interface has been updated. See the new state of compatibility.
